Project 1: Part 1

Project 1 will be to implement a finite element method for a two-point boundary-value problem. It will have several parts.

Warmup: Solving quadratic equations

The quadratic formula says that the solutions of $ax^2 + bx + c = 0$ are given by

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}.$$

If $b^2 - 4ac < 0$ then $\sqrt{b^2 - 4ac}$ is imaginary, so there is no problem with round-off error.

If $b^2 - 4ac > 0$ then cancellation can occur in $-b + \sqrt{b^2 - 4ac}$ if $b > 0$ and in $-b - \sqrt{b^2 - 4ac}$ if $b < 0$. Thus, if $b > 0$ one would want to use the computations

$$x_1 = \frac{-b - \sqrt{b^2 - 4ac}}{2a}, \quad x_2 = \frac{2c}{-b - \sqrt{b^2 - 4ac}}.$$

Similarly if $b < 0$.

Write a function \texttt{(quadratic-solver a b c)} that returns a list of the two roots of $ax^2 + bx + c = 0$ as accurately as possible. Test your code on the following problems:

```

Meroon

Standard Scheme (so-called R5RS Scheme, which Gambit implements) does not have an object system. We use an object system provided by the software package Meroon.

To use Gambit, you need to have `/pkgs/Gambit-C/current/bin/` in your path. The Gambit interpreter is called gsi and the Gambit compiler is called gsc.

To have Gambit load Meroon automatically, just call gsi++ or gsc++.

Our system has two differences with standard Meroon:

1. In standard Meroon, keywords begin with a colon; in our Meroon keywords end with a colon:
   ```scheme
   (define-class Polynomial Object
      ((= variable immutable:)
       (= terms immutable:)))
   ```

2. In standard Meroon, so-called setters begin with `set-` and end with `!`. In our Meroon, setters end with `-set!`:
   ```scheme
   euler-130% gsi++
   [ Meroon V3 Paques2001+1 $Revision: 1.1 $ ]
   Gambit v4.1.2
   > (define-class Point Object (x y))
   Point
   > (define p (make-Point 0 1))
   > (unveil p)
   (a Point <-------------- [Id: 1]
    x: 0
    y: 1 end Point)
   #t
   > (Point-x-set! p 1)
   #<meroon #2>
   > (unveil p)
   (a Point <-------------- [Id: 1]
    x: 1
    y: 1 end Point)
   #t
   >
Numerical Integration

This first part will be about numerical integration (quadrature rules).

The Gauss-Lobatto quadrature rules with \( n \) points have the form

\[
\int_{-1}^{1} f(x) \, dx \approx \frac{2}{n(n-1)} [f(1) + f(-1)] + \sum_{\nu=0}^{n-3} \gamma_{n\nu} f(x_{n\nu}).
\]

Here \( x_{n\nu} \) are the zeros of the degree \( n-2 \) orthogonal polynomial over \([-1,1]\) with the weight

\[
w(x) = 1 - x^2.
\]

If we define

\[
\ell_{n\kappa}(x) = \prod_{\nu=0}^{n} \frac{x - x_{n\nu}}{x_{n\kappa} - x_{n\nu}}
\]

then \( \ell_{n\kappa} \) has degree \( n-1 \) and satisfies

\[
\ell_{n\kappa}(x_{n\nu}) = \begin{cases} 1, & \nu = \kappa, \\ 0, & \nu \neq \kappa. \end{cases}
\]

The weights \( \gamma_{n\nu} \) satisfy

\[
\gamma_{n\nu} = \int_{-1}^{1} \ell_{n,\nu}(x) w(x) \, dx.
\]

So, the first part of the project is to write code to manipulate polynomials. We’re going to start with the code at

and modify it to use Meroon’s framework of classes/objects and generics/methods.

We’ll define a polynomial class:

(\begin{verbatim}
(define-class Polynomial Object
  ((= variable immutable:))
  (= terms immutable:)))
\end{verbatim})

and a way to check whether two Polynomial variables are the same:

(\begin{verbatim}
(define (Polynomial-variable= var1 var2)
  (eq? var1 var2))
\end{verbatim})

The terms of a polynomial is just a list of nonzero terms, in decreasing order by degree (unfortunately called “order” at that web page), so we need some code to manipulate terms and lists of terms:

(\begin{verbatim}
;;; a term is a pair (coeff order) (order should really be degree, but . . .)
;;; (Polynomial-terms p) is a list of terms in decreasing orders.
;;; operation on terms and term-lists
(define (adjoin-term term term-list)
  (if (=zero? (term-coeff term))
    term-list
    (cons term term-list)))
\end{verbatim})
(define (first-term term-list)
  (car term-list))

(define (rest-terms term-list)
  (cdr term-list))

(define (empty-termlist? term-list)
  (null? term-list))

(define (make-term order coeff)
  (list order coeff))

(define (term-order term)
  (car term))

(define (term-coeff term)
  (cadr term))

The web page has code for adding two polynomials. Putting it into our terms we define a generic function add that should work for everything, and we start with it working with numbers:

(define-generic (add (x) y)
  (if (and (number? x)
            (number? y))
      (+ x y)
      (error "add: This generic is not defined on these objects: " x y)))

and then we define a method for adding Polynomials:

(define-method (add (p_1 Polynomial) p_2)
  (cond ((number? p_2)
          (add p1 (number->Polynomial p2 (Polynomial-variable p1))))
        ((and (Polynomial? p_2)
              (Polynomial-variable= (Polynomial-variable p_1)
                                     (Polynomial-variable p_2)))
           (instantiate Polynomial
                          variable: (Polynomial-variable p_1)
                          terms: (add-terms (Polynomial-terms p_1)
                                           (Polynomial-terms p_2))))
        (else
         (error "add: p_2 is neither a number nor a polynomial with the same variable as " p_1 p_2))))

This method is called only when p_1 is a polynomial; if p_2 is a number, it converts p_2 to a Polynomial with the same variable as p_1 and calls add again with both arguments now a Polynomial.

The web page has code for add-terms:

(define (add-terms l1 l2)
  (cond ((empty-termlist? l1) l2)
        ((empty-termlist? l2) l1)
        (else
(let ((t1 (first-term l1))
    (t2 (first-term l2)))
  (cond ((> (term-order t1)
            (term-order t2))
       (adjoin-term t1
           (add-terms (rest-terms l1) l2)))
        ((< (term-order t1)
            (term-order t2))
       (adjoin-term t1
           (add-terms l1 (rest-terms l2))))
        (else
           (adjoin-term
                (make-term (term-order t1)
                            (add (term-coeff t1)
                                 (term-coeff t2)))
                (add-terms (rest-terms l1)
                           (rest-terms l2)))))))

So you need to define number->Polynomial, which takes two arguments.

You need to define a multiply generic that works with numbers by default, and a method for multiply that works on Polynomials; follow the same pattern as for add. The web page has the guts of the code:

(define (multiply-terms l1 l2)
  (if (empty-termlist? l1)
      (the-empty-termlist)
      (add-terms (multiply-term-by-all-terms (first-term l1) l2)
                 (multiply-terms (rest-terms l1) l2)))

(define (multiply-term-by-all-terms t1 L)
  (if (empty-termlist? L)
      (the-empty-termlist)
      (let ((t2 (first-term L)))
        (adjoin-term
         (make-term (+ (term-order t1)
                       (term-order t2))
                    (multiply (term-coeff t1)
                              (term-coeff t2)))
         (multiply-term-by-all-terms t1 (rest-terms L))))))

So that’s pretty much the code that comes on the web page. Meroon defines a generic function show that we can specialize for Polynomials as such:

(define-method (show (p Polynomial) . stream)
  (let ((port (if (null? stream)
                (current-output-port)
                (car stream))))
(if (=zero? p)
  (display 0)
  (show-terms (Polynomial-variable p)
    (Polynomial-terms p)
    port))
(newline port)))
(define (show-terms variable terms port)
  (show-first-term variable (first-term terms) port)
  (for-each (lambda (term)
      (show-term variable term port))
    (rest-terms terms)))
(define (show-first-term variable term port)
  (let ((coeff (term-coeff term))
        (order (term-order term)))
    (display (list (if (and (= coeff 1)
       (positive? order))
       '()
       coeff)
      (cond ((zero? order)'())
        ((= order 1) variable)
        (else
         (list variable "^" order))))))
(define (show-term variable term port)
  (let ((coeff (term-coeff term))
        (order (term-order term)))
    (display (list (if (negative? coeff)
       coeff
       (list "+" coeff))
      (cond ((zero? order)'())
        ((= order 1) variable)
        (else
         (list variable "^" order))))
    port)))

It will probably help your debugging.

So, here are some problems.

(1) The above code uses a function =zero?. Define a generic function =zero? that handles numbers. Define a method that works with Polynomials.

(2) Define a generic function (negate (x)) that handles numbers by default. Define a method for negate that works with Polynomials. Use the generic negate to define a regular function (subtract x y).

(3) Define a function (exponentiate x n) that uses multiply to exponentiate anything that multiply can multiply. Use the discussion of exponentiation on page
(4) Define a function \( \text{variable->Polynomial x} \) that takes a symbol \( x \) and returns a Polynomial that represents the polynomial \( x \), i.e., a single term with coefficient 1 and order 1.

(5) Define a generic function \( \text{evaluate f x} \) that evaluates the function \( f \) at \( x \). If \( f \) is a number, assume that it means a function that constantly returns \( f \). Define a method for Polynomials.

If you've done the exercises until now, something like the following should work.

```scheme
;;;   evaluation
(define-generic (evaluate (f) x)
  (if (number? f)
      f
      (error "evaluate: unknown argument types " f x)))

(define-method (evaluate (p Polynomial) x)
  (evaluate-terms (Polynomial-terms p) x))

(define (evaluate-terms terms x)
  (if (empty-termlist? terms)
      0
      (add (evaluate-term (first-term terms) x)
           (evaluate-terms (rest-terms terms) x))))

(define (evaluate-term term x)
  (multiply (exponentiate x (term-order term))
            (term-coeff term)))
```

Can you write a method that uses Horner’s rule for evaluating Polynomials in our representation?
