A QUANTITATIVE DESCRIPTION OF MESH DEPENDENCE FOR
THE DISCRETIZATION OF SINGULARLY PERTURBED
NONCONVEX PROBLEMS*

ANDREA BRAIDES† AND NUNG KWAN YIP‡

Abstract. We investigate the limiting description for a finite-difference approximation of a sin-
gularly perturbed Allen–Cahn type energy functional. The key issue is to understand the interaction
between two small length-scales: the interfacial thickness \( \varepsilon \) and the mesh size of spatial discretization
\( \delta \). Depending on their relative sizes, we obtain results in the framework of \( \Gamma \)-convergence for the (i)
subcritical (\( \varepsilon \gg \delta \)), (ii) critical (\( \varepsilon \sim \delta \)), and (iii) supercritical (\( \varepsilon \ll \delta \)) cases. The first case leads
to the same area functional as the spatially continuous case while the third gives the same result as
that coming from a ferromagnetic spin energy. The critical case can be regarded as an interpolation
between the two.

Key words. spatial discretization, singularly perturbed problems, nonconvex functionals,
Allen–Cahn functional

1. Introduction. In this paper we describe the effect of discretization by finite
differences on singularly perturbed nonconvex variational problems by examining the
prototypical case of an Allen–Cahn energy

\[
F_\varepsilon(u) = \int_\Omega (W(u) + \varepsilon^2|\nabla u|^2) \, dx,
\]

where \( \Omega \subset \mathbb{R}^n \) and \( W \) is a double-well energy density with wells in \( \pm 1 \); e.g., \( W(u) = (u^2 - 1)^2 \). Except for the trivial constant functions \( u \equiv \pm 1 \) (which can be excluded
by an integral constraint), a function \( u_\varepsilon \) that attains very small energy value \( F_\varepsilon \) (in
the sense that \( F_\varepsilon(u_\varepsilon) = O(\varepsilon) \)) typically partitions the domain \( \Omega \) into subdomains on
which \( u_\varepsilon \) takes the values close to 1 or \(-1 \) and makes a rapid transition between
the subdomains (see Figure 1).

The energy then concentrates on the transition region which is often called the interfacial region. Such a description can be made rigorous using the theory of \( \Gamma \-
convergence of the functionals \( F_\varepsilon \). By now it is well known that as \( \varepsilon \to 0 \) the functional
\( F_\varepsilon \) behave as a sharp-interface phase-transition energy, finite only on functions
taking the values in \( \{\pm 1\} \) and which can be written as an interfacial energy (see, e.g.,
[35, 33, 37]) in the form

\[
\varepsilon C_W \mathcal{H}^{n-1}(\Omega \cap \partial \{u = 1\}),
\]

where \( C_W \) is a constant determined by \( W \) and the boundary of \( \{u = 1\} \) is suitably
defined. In the above \( \mathcal{H}^{n-1} \) is the Hausdorff \((n - 1)\)-dimensional measure which

coincides with the \((n - 1)\)-dimensional surface measure if the surface is a smooth manifold.

Dynamical models associated with energy (1) also arise in many applications. A typical equation, derived from the negative \(L^2\)-gradient flow with respect to (1), is the following Allen–Cahn equation [5]:

\[
 u_t = \epsilon^2 \Delta u - W'(u).
\]

The \(\varepsilon \to 0\) limit of the above equation is also studied in many works. It is shown that the limiting equation is given by the motion of a sharp interface by its mean curvature. See, for example, [25, 16, 30, 27].

Due to their wide range of applications, it is thus of practical importance to consider numerical schemes associated with (1) and (3). In this paper, we only consider stationary problems. Some discussion on dynamical problems will be given. We believe the latter problems are important and yet very challenging.

A formal finite-difference discretization of \(F_\varepsilon\) can be obtained by introducing another small positive parameter \(\delta\) which represents the mesh size. The following energy defined on functions \(u : \Omega \cap \delta \mathbb{Z}^n \to \mathbb{R}\) is a typical example:

\[
 E_{\varepsilon, \delta}(u) = \sum_i \delta^n W(u_i) + \frac{\varepsilon^2}{2} \sum_{i,j} \delta^n \left| \frac{u_i - u_j}{\delta} \right|^2,
\]

where the first sum is taken on \(i \in \Omega \cap \delta \mathbb{Z}^n\) and the second sum on all nearest neighbors (n.n.) \(i, j \in \Omega \cap \delta \mathbb{Z}^n\), i.e., those indices such that \(|i - j| = \delta\). (Each such pair is thus counted twice, which explains the factor 1/2.) The second term is easily shown to be a discretization of \(\varepsilon^2 \int_\Omega |\nabla u|^2 \, dx\). Heuristically, if the discretization step is much smaller than \(\varepsilon\), then the energy \(E_{\varepsilon, \delta}\) is an approximation of the sharp-interface energy (2). This does not happen in the more realistic case when the two scales may interact. We are interested in describing precisely this interaction.

We will first show that (4) is approximated by (2) for \(\delta \ll \varepsilon\). In the case that \(\delta \sim K \varepsilon\) we will show that the \(E_{\varepsilon, \delta}\)'s are approximately

\[
 \varepsilon \int_{\Omega \cap \partial \{u = 1\}} \varphi_K (\nu) d\mathcal{H}^{n-1},
\]

where \(\varphi_K\) is some anisotropic convex energy density characterized by a discrete optimal profile problem. In the case \(\delta \gg \varepsilon\), we have a different scaling of the energies
\[ E_{\varepsilon, \delta}, \text{ which approximate the crystalline interfacial energy} \]

\[ 4 \frac{\varepsilon^2}{\delta} \int_{\Omega \setminus \partial \{ u = 1 \}} \| \nu \|_1 d \mathcal{H}^{n-1}. \]

Moreover, in this last scaling \( E_{\varepsilon, \delta} \) are also approximated by a ferromagnetic spin energy

\[ E_{\varepsilon, \delta}^{\text{ferro}}(u) = \frac{\varepsilon^2}{2\delta} \sum_{i,j} \delta^{n-1} |u_i - u_j|^2 \]

defined for \( u : \Omega \cap \delta \mathbb{Z}^n \to \{-1, 1\} \). Finally, we will show that the function \( \varphi_K \) acts as an interpolation between the euclidean norm \( \| \nu \|_2 \) and the crystalline norm \( 4 \| \nu \|_1 \).

The asymptotic result described in the present paper has some common features with the analysis in the continuum setting the interaction between phase transitions and microscopic oscillations. Examples include the study of energies of the form (see [7, 14, 21])

\[ F_{\varepsilon, \delta}(u) = \int_{\Omega} \left( W(u) + \varepsilon^2 a \left( \frac{x}{\delta} \right) |\nabla u|^2 \right) dx \quad \text{or} \quad \int_{\Omega} \left( W(u, \frac{x}{\delta}) + \varepsilon^2 |\nabla u|^2 \right) dx. \]

(See also [3], where Ising systems with Kac potentials are analyzed.) In the above works, a limiting energy functional in the form of anisotropic sharp interfacial energy is also obtained. In our case the discrete dimension adds a further constraint on the difference quotients, which implies that \( \varphi_K = O(1/K) \) as \( K \to +\infty \).

The main difficulty of the type of problems above is due to the combined presence of singular perturbation and the spatial heterogeneity (which can also come from the discreteness of the problem). When the two scales interact, there can be lots of local minimizers. This phenomenon manifests itself even more profoundly in dynamical problems (see, for example, [38, 26]). Even though there are works which extend the theory of \( \Gamma \)-convergence to evolution equations [36], dynamical versions of the problems described here remain largely open. The work [17] proves the convergence of the time dependent problem of the finite-difference scheme (4) to the motion by mean curvature but only in the subcritical case \( \delta \ll \varepsilon \). On the other hand, the works [19, 31, 23] consider from a homogenization point of view motion by mean curvature in heterogeneous media. A first-order Hamilton–Jacobi equation is derived in the limit. See section 3.5 for further discussion.

2. Setting of the problem. Let \( W : \mathbb{R}^n \to [0, +\infty) \) be a locally Lipschitz double-well potential with wells at \( \pm 1 \); i.e., \( W \) is a nonnegative function and \( W(u) = 0 \) if and only if \( u = 1 \) or \( u = -1 \). Moreover, we suppose that \( W \) is coercive, i.e.,

\[ \lim_{u \to \pm \infty} W(u) = +\infty, \]

and that \( W \) is convex close to \( \pm 1 \), i.e., there exists \( C_0 > 0 \) such that \( \{ u : W(u) \leq C_0 \} \) consists of two intervals on each of which \( W \) is convex. Standard examples include \( W(u) = (1 - u^2)^2 \) or \( W(u) = (1 - |u|)^2 \) (see Figure 2).

Let \( \Omega \) be a bounded open subset of \( \mathbb{R}^n \) with Lipschitz boundary \( \partial \Omega \). We will analyze the asymptotic behavior of \( E_{\varepsilon, \delta} \) defined by (4) on functions \( u : \Omega \cap \delta \mathbb{Z}^n \to \mathbb{R} \) by computing their \( \Gamma \)-developments ([9, section 1] and [13]; see also [10, 20] for a general introduction to \( \Gamma \)-convergence). For completeness, we will briefly state the
necessary definitions at the end of this section. In this process each \( u \) is identified with its piecewise-constant interpolation defined by \( u(x) = u_i \) on \( i + \frac{\delta}{2}(-1,1) \) (and equal to 0 elsewhere) so that \( \Gamma \)-limits can be taken in Lebesgue spaces.

Whatever the dependence of \( \delta \) on \( \epsilon \), the \( \Gamma \)-limit of \( E_{\epsilon,\delta} \) with respect to the weak \( L^1 \)-convergence can be easily shown to be simply

\[
\int_{\Omega} W^{**}(u) \, dx,
\]

where \( W^{**} \) is the convex envelope of \( W \). However, the structure of the interface cannot be described by the above limit. It will only be revealed by the next-order \( \Gamma \)-limit which captures energies at the first relevant scale. This is described by the theorem below. To prepare for its statement and the proof, we denote by \( Q_\nu \) an \( n \)-dimensional cube centered at 0, with side length 1 and one side parallel to \( \nu \), \( Q_\nu^T = TQ_\nu \) for all \( T > 0 \), and \( Q_\nu^T(x) = x + TQ_\nu \) for all \( x \). The limit energies will be defined on \( u \in BV(\Omega; \{\pm 1\}) \) (or equivalently on sets of finite perimeter after identifying \( u \) with \( A = \{u = 1\} \)). For such a \( u \), the jump set \( S_u \) is defined (corresponding to the reduced boundary of \( A \)). Furthermore, on all points of \( S_u \), the measure-theoretical normal \( \nu \), pointing inwards to \( A \), is defined. (We refer to \([8, 29]\) for precise definitions and details.)

**Theorem 2.1.** Let \( \Omega, W, \) and \( E_{\epsilon,\delta} \) be as above, and let \( \delta = \delta(\epsilon) \). We then have the following three regimes for the \( \Gamma \)-limit with respect to the strong \( L^1 \)-convergence.

(i) (subcritical case) If \( \delta \ll \epsilon \) (\( \lim_{\epsilon \to 0} \frac{\delta}{\epsilon} = 0 \)), then we have

\[
\Gamma \text{-} \lim_{\epsilon \to 0} \frac{1}{\epsilon} E_{\epsilon,\delta}(u) = C_W \mathcal{H}^{n-1}(\Omega \cap S_u),
\]

where \( C_W = 2 \int_{-1}^{1} \sqrt{W(s)} \, ds \), as in the continuous case.

(ii) (critical case) If \( \lim_{\epsilon \to 0} \frac{\delta}{\epsilon} = K \) with \( 0 < K < +\infty \), then

\[
\Gamma \text{-} \lim_{\epsilon \to 0} \frac{1}{\epsilon} E_{\epsilon,\delta}(u) = \int_{\Omega \cap S_u} \varphi_K(\nu) \, d\mathcal{H}^{n-1},
\]

where \( \varphi_K \) is given by the asymptotic formula

\[
\varphi_K(\nu) = \lim_{N \to +\infty} \frac{1}{N^{n-1}} \inf \left\{ K \sum_i W(v_i) + \frac{1}{2K} \sum_{i,j} |v_i - v_j|^2 \right\},
\]
where the indices $i,j$ are restricted to the cube $Q^\nu_N$ and the infimum is taken on all $v$ that are equal to $u^\nu(x) = \text{sign}(x,\nu)$ on a neighborhood of $\partial Q^\nu_N$. Furthermore, $\varphi_K$ is continuous in the normal direction $\nu$.

(iii) (supercritical case) If $\varepsilon \ll \delta$ ($\lim_{\varepsilon \to 0} \frac{\varepsilon}{\delta} = 0$), then we have

$$(12) \quad \Gamma^{-}\lim_{\varepsilon \to 0} \frac{\delta}{\varepsilon^2} E_{\varepsilon,\delta}(u) = 4 \int_{\Omega \cap S_u} \|\nu\|_1 \, dH^{n-1},$$

where $\|\nu\|_1 = |\nu_1| + \cdots + |\nu_n|$.

(iv) (interpolation) For all $\nu \in S^{n-1}$ we have

$$(13) \quad \lim_{K \to 0} \varphi_K(\nu) = c_W, \quad \lim_{K \to +\infty} K \varphi_K(\nu) = 4\|\nu\|_1.$$

Remark 2.2. (1) The existence of the limit in (11) and the continuity of $\varphi_K$ can be proved as in the continuous case (see [7]). Moreover, it is a posteriori convex (i.e., its one-homogeneous extension is) since it is the integrand of a lower-semicontinuous interfacial energy (see [6]).

(2) In the one-dimensional case formula (11) reduces to the computation of an optimal-profile problem

$$(14) \quad C_K = \inf \left\{ K \sum_i W(v_i) + \frac{1}{K} \sum_i |v_i - v_{i-1}|^2 : v(\pm\infty) = \pm 1 \right\};$$

in particular (taking $v_i \in \pm 1$ as test functions) we have

$$(15) \quad C_K \leq \frac{4}{K}.$$

(3) It is easily seen that for coordinate directions minimizers for $\varphi_K(e_k)$ are one-dimensional so that

$$\varphi_K(e_k) = C_K,$$

which gives the estimate

$$(16) \quad \varphi_K(\nu) \leq C_K \|\nu\|_1,$$

since the right-hand side is the greatest positively one-homogeneous convex function satisfying $\varphi_K(e_k) = C_K$ for all $k$.

(4) Note that in the supercritical case, the limit interfacial energy is degenerate, or not uniformly convex. This is understandable as in this case the nonlinear term $W(u)$ dominates so that the energy concentrates on the spin functions $v$ which takes on only values of 1 or $-1$. In this case, the energy is equivalent to bond-counting, the number of bonds between 1 and $-1$. It is likely that $\varphi_K$ be uniformly convex for $0 < K < \infty$ even though this is not immediately clear from its definition.

(5) For simplicity, in this paper we do not impose any boundary conditions for the function space. Such effects can be considered. However, boundary layer might arise. In addition, the scaling associated with the boundary conditions might be different from that in the bulk. Hence care must be taken. See, for example, [34, 2] for some works in the continuum case which do consider boundary energy terms.

Further remarks and extensions will be given at the end of this paper. Before the proof, we briefly outline the definition and procedure of proving $\Gamma$-convergence. Given a sequence of functionals $f_\varepsilon : X_\varepsilon \to \mathbb{R}$, it is said to $\Gamma$-converge to $f_0 : X_0 \to \mathbb{R}$ if the following two steps are true:
lower bound: for every $x \in X_0$ and sequence $\{x_{\varepsilon} \in X_\varepsilon\}_{\varepsilon > 0}$ such that $x_{\varepsilon} \rightarrow x_0$, 

\[
(17) \quad \liminf_{\varepsilon \to 0} f_{\varepsilon}(x_{\varepsilon}) \geq f_0(x);
\]

upper bound: given any $x_0 \in X_0$, one can find a sequence $\bar{x}_{\varepsilon} \in X_{\varepsilon}$ such that 

\[
(18) \quad f_0(x_0) \geq \limsup_{\varepsilon \to 0} f_{\varepsilon}(\bar{x}_{\varepsilon}).
\]

The fundamental property of $\Gamma$-convergence is that if the collection of functionals $\{f_{\varepsilon}\}$ is equicoercive (every sequence with equibounded energy has a convergent subsequence), then minimizers of $f_{\varepsilon}$ will have a subsequence that converges to a minimizer of $f_0$.

In the application of this paper, the $X_{\varepsilon}$'s and $X_0$ will be taken to be subspaces of $L^1$. We are most interested in the subspace $BV(\Omega; \{\pm 1\})$ of all functions with bounded variations which take values in $\{\pm 1\}$ which can also be identified with sets of finite perimeter. We will use in particular the well-known result by Modica and Mortola (see [35]) that

\[
(19) \quad \Gamma\text{-limsup}_{\varepsilon \to 0} \frac{1}{\varepsilon} F_{\varepsilon}(u) = C W \mathcal{H}^{n-1}(\Omega \cap S_u)
\]

with domain $u \in BV(\Omega; \{\pm 1\})$. In this case the sequence of energies is equicoercive in $L^1(\Omega)$.

Beside the $\Gamma$-limit defined above, it is useful to introduce the $\Gamma$-lower and upper limits, respectively, as

\[
(20) \quad f'(x) := \Gamma\text{-liminf}_{\varepsilon \to 0} f_{\varepsilon}(x) = \inf \left\{ \liminf_{\varepsilon \to 0} f_{\varepsilon}(x_{\varepsilon}) : x_{\varepsilon} \rightarrow x \right\},
\]

\[
(21) \quad f''(x) := \Gamma\text{-limsup}_{\varepsilon \to 0} f_{\varepsilon}(x) = \inf \left\{ \limsup_{\varepsilon \to 0} f_{\varepsilon}(x_{\varepsilon}) : x_{\varepsilon} \rightarrow x \right\},
\]

which are always defined at all $x$. The desired lower bound then translates into $f'(x) \geq f_0(x)$ and the upper bound into $f''(x) \leq f_0(x)$.

The $\Gamma$-lower and upper limits are lower-semicontinuous functions [9, Proposition 1.28]. This is useful in the computation of the lower inequality, since it allows us to restrict to classes of lower-semicontinuous $f_0$, which in the present paper will be surface energies with a convex integrand of the normal. Moreover, it allows us also to restrict the verification of the upper bound to a dense class of $x$ (see [9, Remark 1.29]), which in our case will be (functions identified with) polyhedral sets.

3. Proof of the result. In the two extreme cases (i) and (iii) the proof will be achieved by a “separation of scales” argument. First, a lower bound is obtained by comparing the energies with the functionals that are formally obtained by letting, respectively, $\delta \to 0$ with $\varepsilon > 0$ fixed and $\varepsilon \to 0$ with $\delta > 0$ fixed. Second, the bounds will be proved to be sharp by using suitable approximate (or recovering) sequences. In the intermediate case, a new surface energy defined directly by a family of scaled discrete problems has to be constructed.

As is customary, the letter $C$ will denote a strictly positive constant whose value may vary at each of its appearance.

3.1. Subcritical case ($\delta \ll \varepsilon$). We will first show that given $\{u_{\varepsilon}\}$ with $
\sup_{\varepsilon} \frac{1}{\varepsilon} E_{\varepsilon, \delta}(u_{\varepsilon}) \leq C < +\infty$, we can construct continuous functions $v_{\varepsilon}$ such that
\[ \|u_\varepsilon - u_\varepsilon\|_{L^1} = o(1) \]

and

\[ \liminf_{\varepsilon} \frac{1}{\varepsilon} E_{\varepsilon, \delta}(u_\varepsilon) \geq \liminf_{\varepsilon} \frac{1}{\varepsilon} F_\varepsilon(v_\varepsilon). \]

By the equicoerciveness of \( \frac{1}{\varepsilon} F_\varepsilon \), this implies that we may suppose up to subsequences that \( v_\varepsilon \to u \) and hence \( u_\varepsilon \to u \) in \( L^1(\Omega) \).

If \( u_\varepsilon \to u \), then from the inequality above and (19) we have

\[ \liminf_{\varepsilon} \frac{1}{\varepsilon} E_{\varepsilon, \delta}(u_\varepsilon) \geq \liminf_{\varepsilon} \frac{1}{\varepsilon} F_\varepsilon(v_\varepsilon) \geq C_W H^{n-1}(\Omega \cap S_u), \]

i.e., the lower bound (17) for \( \frac{1}{\varepsilon} E_{\varepsilon, \delta} \).

To start the proof, upon a truncation argument, we can first suppose that \( \|u_\varepsilon\|_\infty \leq 1 \). Next we consider the continuous functions \( v_\varepsilon \) mentioned above to be the piecewise-affine interpolations on a triangulation of \( u_\varepsilon \). Then we have

\[ \frac{1}{2} \sum_{i,j} \delta^\alpha \left| \frac{u_i^\varepsilon - u_j^\varepsilon}{\delta} \right|^2 = \int_\Omega |\nabla v_\varepsilon|^2 \, dx + o(1). \]

Next we have to estimate the first sum in \( E_{\varepsilon, \delta}(u_\varepsilon) \) in terms of \( \int_\Omega W(v_\varepsilon) \, dx \). We will consider the various cases whether \( u_i^\varepsilon \) together with the values of its nearest neighbors fall into the same convexity region of \( W(\cdot) \).

The first and simple scenario is that when for all the neighbors \( j \) of \( i \), the values \( u_i \) and \( u_j \) lie in the same interval of convexity of \( W \) as in this case we have by Jensen’s inequality,

\[ \int_{T^\delta} W(v_\varepsilon) \, dx \leq \frac{1}{n+1} |T^\delta| \sum_{k \in \text{Vertices}(T^\delta)} W(u_k^\varepsilon) \]

for each simplex \( T^\delta \) of the triangulation with vertices on \( \delta Z^n \), where \( v_\varepsilon \) is a convex combination of the value \( u_k^\varepsilon \) at the vertices of \( T^\delta \) and one of the vertices is \( i \) as above.

To continue, let \( C_0 \) be a fixed number such that \( \{ z : W(z) < C_0 \} \) consists of two intervals. Denote by \( J_i^\varepsilon \) the set of indices \( i \) such that \( W(u_i^\varepsilon) < C_0/2 \) and the value \( u_j^\varepsilon \) of each its nearest neighbor \( j \) is in the same interval of \( \{ z : W(z) < C_0 \} \) as \( u_i^\varepsilon \), and denote by \( J_j^\varepsilon \) the complement of \( J_i^\varepsilon \) in \( \{ i : W(u_i^\varepsilon) < C_0/2 \} \). If the simplex \( T^\delta \) as above is such that one of its vertices is in \( J_i^\varepsilon \), then (23) holds by the observation above. As for the simplexes with one vertex in \( J_i^\varepsilon \), note that

\[ C \geq \sum_{i \in J_i^\varepsilon} \delta^\alpha \cdot \left| \frac{u_i^\varepsilon - u_j^\varepsilon}{\delta} \right|^2 \geq C' \frac{\delta^{n-1}}{\delta} \#(J_i^\varepsilon) \]

so that

\[ \#(J_i^\varepsilon) = o \left( \frac{1}{\delta^{n-1}} \right). \]

As a consequence, if we sum over all such simplexes and simply take into account that \( W \) is bounded on \([-1, 1]\] we have

\[ \frac{1}{\varepsilon} \sum_{T^\delta \in J_i^\varepsilon} \int_{T^\delta} W(v_\varepsilon) \, dx \leq C \frac{\delta^n}{\varepsilon} \#(J_i^\varepsilon) = o \left( \frac{1}{\varepsilon} \right). \]
In the above and the following, we will make use of the abused notation that $T_{\varepsilon} \in J_{\varepsilon}^2$ if any of the vertices of $T_{\varepsilon}$ belongs to $J_{\varepsilon}^2$. It applies to other set of indices also.

We now take into account simplexes for which the functions $u_{\varepsilon}$ may take values outside the convexity domain of $W$. To this end, with fixed $M > 0$, denote by $I_{\varepsilon}^1$ and $I_{\varepsilon}^2$ the sets of indices

$$I_{\varepsilon}^1 = \left\{ i : W(u_{\varepsilon}^i) > C_0/2, \quad \left| u_{\varepsilon}^i - u_{\varepsilon}^j \right| \leq \frac{M}{\varepsilon} \text{ for all n.n.j} \right\},$$

$$I_{\varepsilon}^2 = \left\{ i : W(u_{\varepsilon}^i) > C_0/2, \quad \left| u_{\varepsilon}^i - u_{\varepsilon}^j \right| > \frac{M}{\varepsilon} \text{ for some n.n.j} \right\}.$$

Since

$$\frac{\delta^n}{\varepsilon} \#(I_{\varepsilon}^1 \cup I_{\varepsilon}^2) \frac{C_0}{2} \leq \frac{1}{\varepsilon} \sum_i \delta^n W(u_{\varepsilon}^i) \leq C$$

and

$$\frac{\delta^n}{\varepsilon} \#(I_{\varepsilon}^2) \left( \frac{C_0}{2} + \frac{1}{4} M^2 \right) \leq \frac{1}{\varepsilon} \sum_i \delta^n W(u_{\varepsilon}^i) + \frac{\varepsilon}{4} \sum_{i,j} \delta^n \left| \frac{u_{\varepsilon}^i - u_{\varepsilon}^j}{\delta} \right|^2 \leq C$$

we have

$$\#(I_{\varepsilon}^1 \cup I_{\varepsilon}^2) \leq C \frac{\varepsilon}{\delta^n}, \quad \#(I_{\varepsilon}^2) \leq \frac{C}{(1 + M^2)^2} \frac{\varepsilon}{\delta^n}. \tag{25}$$

Let $T^\delta$ be a simplex as above, and suppose that one of its vertices $i$ is in $I_{\varepsilon}^1$; then by the Lipschitz continuity of $W$ 1 vertices $k$ of $T^\delta$ we have

$$\left| \int_{T^\delta} W(v_{\varepsilon}) \, dx - \left| T^\delta \right| W(u_{\varepsilon}^k) \right| \leq \frac{1}{\varepsilon} C \delta^n \sup_{i,j} \left| u_{\varepsilon}^j - u_{\varepsilon}^i \right| \leq C \frac{\delta^{n+1}}{\varepsilon} M$$

so that

$$\left| \int_{T^\delta} W(v_{\varepsilon}) \, dx - \frac{1}{n+1} \left| T^\delta \right| \sum_k W(u_{\varepsilon}^k) \right| \leq C \delta^n \sup_{i,j} \left| u_{\varepsilon}^j - u_{\varepsilon}^i \right| \leq C \frac{\delta^{n+1}}{\varepsilon} M.$$

Summing over such $T^\delta$ and taking into account (25) we have

$$\frac{1}{\varepsilon} \sum\int_{T^\delta} W(v_{\varepsilon}) \, dx - \frac{1}{\varepsilon} \frac{1}{n+1} \left| T^\delta \right| \sum_k W(u_{\varepsilon}^k) \right| \leq \#(I_{\varepsilon}^1) C \frac{\delta^{n+1}}{\varepsilon} = \mathcal{O}(1). \tag{26}$$

Next, if we sum over all simplexes with one vertex in $I_{\varepsilon}^2$, and again simply take into account that $W$ is bounded on $[-1, 1]$, by (25) we have

$$\frac{1}{\varepsilon} \sum\int_{T^\delta} W(v_{\varepsilon}) \, dx \leq C \frac{\delta^n}{\varepsilon} \#(I_{\varepsilon}^2) \leq \frac{C}{1 + M^2}. \tag{27}$$

Taking into account the estimates in (23), (24), (26), and (27) we then obtain

$$\frac{1}{\varepsilon} \int_{\Omega} W(v_{\varepsilon}) \, dx \leq \frac{1}{\varepsilon} \sum_{T^\delta} \frac{1}{n+1} \left| T^\delta \right| W(u_{\varepsilon}^k) + \mathcal{O}(1) + \frac{C}{1 + M^2}
\leq \frac{1}{\varepsilon} \sum_i \delta^n W(u_{\varepsilon}^i) + \mathcal{O}(1) + \frac{C}{1 + M^2}. \tag{28}$$
Finally, by (22), (28), and the arbitrariness of $M > 0$ we have
\begin{equation}
\liminf_{\varepsilon \to 0} \frac{1}{\varepsilon} E_{\varepsilon, \delta}(u_{\varepsilon}) \geq \liminf_{\varepsilon \to 0} \int_{\Omega} \left( \frac{1}{\varepsilon} W(v_{\varepsilon}) + \varepsilon |\nabla v_{\varepsilon}|^2 \right) dx
= \liminf_{\varepsilon \to 0} \frac{1}{\varepsilon} F_{\varepsilon}(v_{\varepsilon}).
\end{equation}

As noted at the beginning of the section, from this inequality we deduce the equicoerciveness of the sequence $\frac{1}{\varepsilon} E_{\varepsilon, \delta}$ with respect to the strong $L^1$-convergence since the functionals $\frac{1}{\varepsilon} F_{\varepsilon}$ are equicoercive and the construction above implies that $\|u_{\varepsilon} - v_{\varepsilon}\|_1 = o(1)$ as $\varepsilon \to 0$, as well as the desired lower bound.

The upper bound (18) is obtained by an explicit construction. It is sufficient to show that it holds for $S_u$ a planar interface, since the generalization to a general interface is achieved by the same approximation using polyhedral interfaces as in the continuum case (see, for example, [1, section 3.9]). We can also suppose that $\mathcal{H}^{n-1}(S_u \cap \partial \Omega) = 0$.

Now consider $u(x) = \text{sign}(x, \nu)$. Let $v$ be a minimizer for the optimal profile problem giving $C_W$; i.e., $v(\pm \infty) = \pm 1$ and
\begin{equation}
\int_{-\infty}^{+\infty} \left( W(v) + |v'|^2 \right) dt = C_W.
\end{equation}

The recovery sequence $(u_{\varepsilon})$ is then defined by
\begin{equation}
u_{i, \varepsilon} = v \left( \frac{1}{\varepsilon}(i, \nu) \right), \quad i \in \delta \mathbb{Z}^n;
\end{equation}
i.e., it is the discretization of $v((x, \nu)/\varepsilon)$ on the lattice $\delta \mathbb{Z}^n$.

After noting that if $i - j = \delta e_k$,
\begin{equation}
u_{i, \varepsilon} - \nu_{j, \varepsilon} = \frac{\nu_k}{\varepsilon} v' \left( \frac{1}{\varepsilon}(i, \nu) \right) (1 + o(1)) ,
\end{equation}
we have for fixed $i$
\begin{equation}rac{\varepsilon}{2} \delta^n \sum_{k=1}^{n} \delta^n \left| \frac{u_{i, \varepsilon} - u_{i+\delta e_k, \varepsilon}}{\delta} \right|^2 = \delta^n \sum_{k=1}^{n} \nu_k^2 \left| v' \left( \frac{1}{\varepsilon}(i, \nu) \right) (1 + o(1)) \right|^2
= \delta^n \left| v' \left( \frac{1}{\varepsilon}(i, \nu) \right) \right|^2 (1 + o(1)),
\end{equation}
so that
\begin{equation}rac{1}{\varepsilon} E_{\varepsilon, \delta}(u_{\varepsilon}) = \sum_{i} \delta^n \left( \frac{1}{\varepsilon} W \left( v \left( \frac{1}{\varepsilon}(i, \nu) \right) \right) + \frac{1}{\varepsilon} v' \left( \frac{1}{\varepsilon}(i, \nu) \right) \right) (1 + o(1))
= C_W \mathcal{H}^{n-1}(S_u \cap \Omega) + o(1).
\end{equation}

3.2. Critical case ($0 < \lim_{\varepsilon \to 0} \frac{\delta}{\varepsilon} = K < \infty$). In this case, the proof of the equicoerciveness can be achieved through reduction to the one-dimensional case by a sectional compactness criterion [1, section 3.7]. In dimension one, the proof is standard and can be obtained following [9, section 6.2] by replacing integrals with sums. This procedure also shows that the limit is in $BV(\Omega; \{\pm 1\})$. 

The proof of the lower bound can be achieved by a blow-up procedure as follows. Let \( \sup \frac{1}{\varepsilon} E_{\varepsilon, \delta}(u_{\varepsilon}) < +\infty \) and \( u_{\varepsilon} \to u \). By equicoercivity (as mentioned above) \( u \in BV(\Omega; \{\pm 1\}) \). For each \( \varepsilon > 0 \) we consider the measures

\[
\mu_{\varepsilon} = \sum_i \delta^{n} \left( \frac{1}{\varepsilon} W(u_{\varepsilon}^i) + \frac{\varepsilon}{2} \sum_{k=1}^{n} \frac{|u_{\varepsilon}^i - u_{\varepsilon}^i + \varepsilon \delta e_k|^{2}}{\delta} \right) \mathbf{1}_{\delta i}
\]

(to avoid confusing notation \( \mathbf{1}_{x} \) denotes the Dirac delta in \( x \)), where the sum is performed on all \( i \in \Omega \cap \delta \mathbb{Z}^{n} \) such that \( i + \delta e_k \in \Omega \cap \delta \mathbb{Z}^{n} \) for all \( k = 1, \ldots, n \).

Note that \( \frac{1}{\varepsilon} E_{\varepsilon, \delta}(u_{\varepsilon}) \geq \mu_{\varepsilon}(\Omega) \) so that the family of measures \( \mu_{\varepsilon} \) is equibounded. Hence, up to further subsequences we can assume that \( \mu_{\varepsilon} \) converges weak-* to a finite measure \( \mu \). To continue, we will estimate \( \mu \) on \( S_{u} \). For this, we will use a covering argument for almost all \( S_{u} \) with cubes.

With fixed \( h \in \mathbb{N} \), we consider the collection \( Q_{h} \) of cubes \( Q_{\nu \rho}(x) \) such that the following conditions are satisfied:

(a) \( x \in S_{u} \) and \( \nu = \nu(x) \) is the normal to \( S_{u} \) at \( x \);
(b) \( |(Q_{\nu \rho}(x) \cap \{u = 1\}) \triangle \Pi^{u}(x)| \leq \frac{1}{h} \rho^{n} \), where

\[
\Pi^{u}(x) = \{ y \in \mathbb{R}^{n} : \langle y - x, \nu \rangle \geq 0 \};
\]

(c) \( \left| \frac{\mu(Q_{\nu \rho}(x))}{\rho^{n}} - \frac{d\mu}{d\mathcal{H}^{n-1}}(x) \right| \leq \frac{1}{h} \); \hspace{1cm}
(d) \( \left| \frac{1}{\rho^{n}} \int_{Q_{\nu \rho}(x) \cap S_{u}} \varphi_{K}(\nu(y)) d\mathcal{H}^{n-1}(y) - \varphi_{K}(\nu(x)) \right| \leq \frac{1}{h} \); and

(e) \( \mu(Q_{\nu \rho}(x)) = \mu(Q_{\nu \rho}(x)) \).

(The notation in (a)–(e) is pictured in Figure 3.)

Note that for fixed \( x \in S_{u} \) and for \( \rho \) small enough, (b) is satisfied by the definition of \( S_{u} \) since its blow-up set is a hyperplane. Condition (c) follows from the Besicovitch derivation theorem provided that

\[
\frac{d\mu}{d\mathcal{H}^{n-1}}(x) < +\infty;
\]

Condition (d) holds by the same reason, and (e) is satisfied for almost all \( \rho > 0 \) since \( \mu \) is a finite measure and hence \( \mu(\partial Q_{\nu \rho}(x)) = 0 \) except for at most countably many
\(\rho\)'s. We deduce that \(Q_\rho\) is a fine covering of the set

\[ S_\rho^u = \left\{ x \in S_u : \frac{d\mu}{dH^{n-1}}(x) < +\infty \right\}. \]

By Morse's lemma [28, Theorem 1.147], we can extract a countable family of disjoint closed cubes \(\{Q^\mu_{\rho_i}(x_j)\}\) still covering \(S_\rho^u\). Note that we have

\[ H^{n-1}(S_u \setminus S_\rho^u) = 0 \]

since \(\mu(S_u) < +\infty\).

We now fix an \(x \in S_\rho^u\). For simplicity, it is assumed to be 0. In addition, let \(Q^\nu_{\rho} = Q^\nu_{\rho}(0)\) be a cube satisfying (b)–(c) above. Then for \(\varepsilon\) small enough we have

\[ \int_{Q^\nu_{\rho}} |u_\varepsilon - u^\nu| \, dy \leq \frac{4}{\varepsilon} \rho^n \]

by (b) above, where \(u^\nu(x) = \text{sign}(x, \nu)\). Note that in this regime we have

\[ \liminf_{\varepsilon \to 0} \frac{\mu_\varepsilon(Q^\nu_{\rho}(x))}{\rho^{n-1}} \]

(with a slight abuse of notation we identify \(u^\nu\) with its restriction to \(\delta\mathbb{Z}^n\)) and that the same estimate holds locally. By (30) and (31), it is not restrictive to suppose that \(u_\varepsilon = u^\nu\) near the boundary of \(Q^\nu_{\rho}\). This can be done by using a well-chosen cutoff function close to \(\partial Q^\nu_{\rho}\). This procedure will introduce only an error in the energy functional of order \(O(1/\varepsilon)\rho^{n-1}\). (This is a classical argument in \(\Gamma\)-convergence dating back to De Giorgi (see [24]). For its formalization in a discrete-to-continuous setting we refer, e.g., to [12]).

We then have

\[ \liminf_{\varepsilon \to 0} \frac{\mu_\varepsilon(Q^\nu_{\rho}(x))}{\rho^{n-1}} \]

\[ = \liminf_{\varepsilon \to 0} \frac{1}{\rho^{n-1}} \left( \sum_{i \in \delta \mathbb{Z}^n \cap Q^\nu_{\rho}} \delta^n \left( \frac{1}{\varepsilon} W(u^\varepsilon_i) + \frac{\varepsilon}{2} \sum_{k=1}^n \delta^n \frac{|u^\varepsilon_i - u^\varepsilon_{i+k\delta}|^2}{\delta} \right) \right) + O\left(\frac{1}{\varepsilon}\right) \]

\[ = \liminf_{\varepsilon \to 0} \left( \frac{1}{\varepsilon^{n-1}} \left( \sum_{i \in \mathbb{Z}^n \cap Q^\nu_{\rho}} \left( \frac{1}{\varepsilon} W(u^\varepsilon_i) + \frac{\varepsilon}{2\delta} \sum_{k=1}^n |u^\varepsilon_i - u^\varepsilon_{i+k\delta}|^2 \right) \right) + O\left(\frac{1}{\varepsilon}\right) \]

where \(N_\varepsilon = \rho/\delta\), \(K_\varepsilon = \rho/\varepsilon\), and \(w^\varepsilon_i = u^\varepsilon_i\) for \(i \in \mathbb{Z}^n\). Since the functions \(w^\varepsilon\) are suitable test functions for the problem in (11) we obtain

\[ \liminf_{\varepsilon \to 0} \frac{\mu_\varepsilon(Q^\nu_{\rho}(x))}{\rho^{n-1}} \geq \varphi_K(\nu(x)) + O\left(\frac{1}{\varepsilon}\right). \]
Using condition (d) above, we finally deduce that
\[
\liminf_{\varepsilon \to 0} \mu_\varepsilon(\Omega) \geq \sum_j \liminf_{\varepsilon \to 0} \mu_\varepsilon(Q_{\rho_j}(x_j) \cap S_u) + O\left(\frac{1}{n}\right)
\geq \sum_j \int_{Q_{\rho_j}(x_j) \cap \Omega} \varphi_K(\nu(y)) \, d\mathcal{H}^{n-1}(y) + O\left(\frac{1}{n}\right)
= \int_{\Omega \cap S_u} \varphi_K(\nu(y)) \, d\mathcal{H}^{n-1}(y) + O\left(\frac{1}{n}\right),
\]
which gives the liminf inequality by the arbitrariness of \( h \).

For the upper bound, we again treat explicitly the case \( u(x) = \text{sign} \, x_n \) only. For this it is not restrictive to suppose that \( \mathcal{H}^{n-1}(S_u \cap \partial\Omega) = 0 \). We fix \( \eta > 0 \), \( N \in \mathbb{N} \), and \( \nu \) as a test function for the problem in (11) such that
\[
\frac{1}{N^{n-1}} \left( K \sum_{i \in Q_N} W(v_i) + \frac{1}{2K} \sum_{i,j \in Q_N} |v_i - v_j|^2 \right) \leq \varphi_K(\eta_n) + \eta.
\]
We may extend \( u_\varepsilon \) periodically in the directions \( x_1, \ldots, x_{n-1} \) inside the strip \( \{|x_n| \leq N/2\} \) and equal to \( u \) (i.e., constant \( \pm 1 \)) outside this strip. We then set
\[
u_i = \nu_{i/\delta} \quad \text{for} \quad i \in \delta\mathbb{Z}^n.
\]
For such \( u_\varepsilon \), we have
\[
\frac{1}{\varepsilon} E_{\varepsilon,\delta}(u_\varepsilon) \leq \delta^{n-1} \# \left\{ j \in \mathbb{Z}^{n-1} : (\delta Q_N + \delta j) \cap \Omega \neq \emptyset \right\}
\times \left( \sum_{i \in \delta Q_N} \frac{\delta}{\varepsilon} W(u_i) + \sum_{i,j \in Q_N} \frac{\varepsilon}{2\delta} |u_i - u_j|^2 \right)
= (\mathcal{H}^{n-1}(S_u \cap \Omega) + o(1)) \left( \sum_{i \in Q_N} \frac{\delta}{\varepsilon} W(v_i) + \sum_{i,j \in Q_N} \frac{\varepsilon}{2\delta} |v_i - v_j|^2 \right)
\leq \mathcal{H}^{n-1}(S_u \cap \Omega) \left( \varphi_K(\eta_n) + \eta \right) + o(1)
\]
as \( \varepsilon \to 0 \), which proves the upper inequality by the arbitrariness of \( \eta > 0 \). The case of a general \( \nu \) is proven likewise with an almost-periodic extension of \( \nu \) in the directions orthogonal to \( \nu \) (see, e.g., [12]). As remarked above this is sufficient to infer the validity of the upper bound for all \( u \) by approximation.

3.3. Supercritical case \( (\varepsilon \ll \delta) \). In this case, formally letting \( \varepsilon \to 0 \), we obtain the constraint \( u_i \in \{ \pm 1 \} \) for all \( i \). This suggests to use as a comparison functional the “spin energies”
\[
G_\delta(u) = \left\{ \begin{array}{ll}
\sum_{i,j} \delta^{n-1} |u_i - u_j|^2 & \text{if } |u_i| = 1 \text{ for all } i, \\
+\infty & \text{otherwise}.
\end{array} \right.
\]
These energies have been studied in [4]. They are equicoercive in \( L^1 \), their \( \Gamma \)-limit is finite only on \( BV(\Omega; \{ \pm 1 \}) \), and
\[
\Gamma_{\delta \to 0} \lim G_\delta(u) = 4 \int_{S_u \cap \Omega} \|\nu\|_1 \, d\mathcal{H}^{n-1}.
\]
Now consider a sequence \( u_\varepsilon \) with \( \sup_\varepsilon (\delta/\varepsilon^2) E_{\varepsilon, \delta}(u_\varepsilon) < +\infty \); i.e.,

\[
\sum_i \frac{\delta^{n+1}}{\varepsilon^2} W(u_i^\varepsilon) + \sum_{i,j} \delta^{n-1} |u_i^\varepsilon - u_j^\varepsilon|^2 \leq C .
\]

From (36) in particular, for all \( \eta > 0 \) we have

\[
\# \{ i : W(u_i^\varepsilon) > \eta \} \leq \frac{C}{\eta} \frac{\varepsilon^2}{\delta^{n+1}} = o(1) \frac{1}{\delta^{n-1}}
\]

for \( \varepsilon \) small enough.

If we define

\[
v_i^\varepsilon = \begin{cases} 
1 & \text{if } u_i^\varepsilon > 0, \\
-1 & \text{if } u_i^\varepsilon \leq 0,
\end{cases}
\]

then condition (37) ensures that

\[
\| u_\varepsilon - v_\varepsilon \|_1 \leq C \eta + o(\delta)
\]

and in particular \( \| u_\varepsilon - v_\varepsilon \|_1 \to 0 \) by the arbitrariness of \( \eta \). We can estimate

\[
\frac{\delta}{\varepsilon^2} E_{\varepsilon, \delta}(u_\varepsilon) \geq C_\eta G_\delta(v_\varepsilon)
\]

with \( C_\eta \to 1 \) as \( \eta \to 0 \) so that

\[
\liminf_{\varepsilon \to 0} \frac{\delta}{\varepsilon^2} E_{\varepsilon, \delta}(u_\varepsilon) \geq \liminf_{\varepsilon \to 0} G_\delta(v_\varepsilon).
\]

This implies the coerciveness of the energies \( (\delta/\varepsilon^2) E_{\varepsilon, \delta} \) and the desired lower bound.

The proof of the upper bound is trivial since on the domain of \( G_\delta \) we have

\[
\frac{\delta}{\varepsilon^2} E_{\varepsilon, \delta} = G_\delta.
\]

It suffices then to take a sequence \( u_\varepsilon = v_\delta \), where \( v_\delta \to u \) realizes the upper bound for the \( \Gamma \)-limit in (35).

### 3.4. Interpolation.

Note that in the proof of the lower inequality, the condition \( \delta \ll \varepsilon \) was used only in the estimate leading to (24). So if now \( \varepsilon/\delta \to K \), then we get instead

\[
\#(J^2_\varepsilon) = \frac{1}{\delta^{n+1}} O(K) ,
\]

which gives a \( O(K) \) in (24), and as a consequence

\[
\liminf_{\varepsilon \to 0} \frac{1}{\varepsilon} E_{\varepsilon, \delta}(u_\varepsilon) \geq \left(C_W + O(K)\right) \mathcal{H}^{n-1}(\Omega \cap S_u).
\]

in (29). This proves that

\[
\liminf_{K \to 0^+} \varphi_K(\nu) \geq C_W.
\]
The opposite inequality with the lim sup is obtained by estimating $\varphi_K$ taking $v_i$ as in the proof of the upper bound in the case subcritical case.

Finally, by (15) and (16) in Remark 2.2(ii) we obtain
\[
\limsup_{K \to +\infty} K \varphi_K(v) \leq 4 \|v\|_1.
\]

The opposite inequality for the liminf follows from the estimate
\[
\frac{K}{\varepsilon} E_{\varepsilon, \delta}(u) \geq (1 + o(1)) \frac{1}{2} \sum_{i,j} \delta^{n-1} |u_i - u_j|^2
\]
and the same argument as after (38).

3.5. Remarks and extensions. As mentioned in the introduction, due to the wide range of applications of singularly perturbed problems, analysis and understanding of their numerical schemes are of practical importance. However, mesh size introduces another small length scale which in essentially all practical settings interacts with the small parameter in the original problem. Such an interaction already gives nontrivial descriptions for the stationary problem, as indicated by our theorem. In this section, we give some further remarks and plausible extensions of our results.

It is natural to perform a similar analysis for dynamical problems, such as (3). The situation can be quite intricate due to the presence of a large number of critical points or local minimizers for the discrete functional. This can lead to interesting pinning and de-pinning phenomena. Such have been investigated in both the continuum and discrete cases (see, for example, [22, 15]). The more recent work [11] is closer in spirit with the current paper, in particular the supercritical case. A time stepping, variational scheme is employed on a lattice model. Depending on the relative magnitude of the mesh and time step sizes, the dynamics demonstrates interesting stick-slip phenomena.

Even though our results do not directly lead to concrete statements for dynamical problems, it does give a quantitative description of the limit interfacial energy functional and more important, the energy scaling in different regimes of $\varepsilon$ and $\delta$. They can also provide useful guidelines if other effects are incorporated. Here we provide some examples.

Volume constraints can be imposed:
\[
\sum_i \delta^n u_i = C_\delta.
\]
If $C_\delta \to C$, the same $\Gamma$-limit appears as before but with the constraint for the limit $u$,
\[
\int_\Omega u = C.
\]

Applied forces can also be considered:
\[
E_{\varepsilon, \delta}(u) = \sum_i \delta^n W(u_i) + \frac{\varepsilon}{2} \sum_{i,j} \delta^n \frac{|u_i - u_j|}{\delta}^2 + \sum_i \delta^n f^{\varepsilon, \delta}_i u_i.
\]

If the forcing terms $f^{\varepsilon, \delta}$ satisfy
\[
\frac{1}{\varepsilon} f^{\varepsilon, \delta} \overset{L^2}{\to} f \quad \text{in (i) and (ii)}
\]
\[
\frac{\delta}{\varepsilon^2} f^{\varepsilon, \delta} \overset{L^2}{\to} f, \quad \text{(iii)},
\]
then the $\Gamma$-limit is the same with the addition of the bulk integral term,

$$\int_{\Omega} f u \, dx.$$ 

A complete picture of discrete dynamics is not currently available. However, our results can shed light in the realistic critical case (ii) if $K \ll 1$ and $K \gg 1$. For the former case, we believe it is possible to compute asymptotically the limiting dynamics and investigate the underlying anisotropy front propagation. For the latter case, the approach of [11] might still be applicable. This resembles some works in the study of cell-dynamical systems [18, 32]. Stochastic noise can certainly be used to drive the state out of local minima. The incorporation of a nonuniform adaptive mesh is also possible if we have some a priori knowledge about the location of the interface. We will defer quantitative answers to these challenging questions in future works.

Acknowledgments. The authors would like to thank Robert Kohn for useful discussion of the problem. The hospitality of the IMA where this work originated is also appreciated.
