# Brownian motion

## Definition 1.

Let

- $(\Omega, \mathcal{F}, P)$  probability space
- $\{B_t; t \geq 0\}$  stochastic process,  $\mathbb{R}$ -valued

We say that  $B$  is a **Brownian motion** if:

- 1  $B_0 = 0$  almost surely
- 2  $B$  is Gaussian centered
- 3 For  $0 \leq s < t$  we have

$$\mathbb{E} [(B_t - B_s)^2] = (t - s)$$

# Brownian motion is non smooth ( $B \in \mathcal{C}^{1/2-\varepsilon}$ )

# Illustration: Brownian motion is random

# Fractional Brownian motion

## Definition 2.

Let

- $(\Omega, \mathcal{F}, P)$  probability space and  $H \in (0, 1)$
- $\{B_t^H; t \geq 0\}$  stochastic process,  $\mathbb{R}$ -valued

We say that  $B^H$  is a **fractional Brownian motion** if:

- 1  $B_0^H = 0$  almost surely
- 2  $B^H$  is Gaussian centered
- 3 For  $0 \leq s < t$  we have

$$\mathbb{E} \left[ (B_t^H - B_s^H)^2 \right] = (t - s)^{2H}$$

# Examples of fBm paths ( $B \in \mathcal{C}^{H-\varepsilon}$ )

$H = 0.3$

$H = 0.5$

$H = 0.7$

# Noises

White noise: We have

- $\dot{B}$  = distributional derivative of  $B$
- Regularity:  $\dot{B}$  element of Besov space  $\mathcal{B}^{-1/2-\varepsilon}$
- Covariance:

$$\mathbb{E} \left[ \dot{B}_t \dot{B}_s \right] = \delta(t - s)$$

Colored noise: Defined as

- $\dot{B}^H$  = distributional derivative of  $B^H$
- Regularity:  $\dot{B}^H$  element of Besov space  $\mathcal{B}^{-(1-H+\varepsilon)}$
- Covariance: can also be a distribution

$$\mathbb{E} \left[ \dot{B}_t^H \dot{B}_s^H \right] = |t - s|^{-(2-2H)}$$

# Model for the noise in $\mathbb{R}^d$

Covariance function for  $\dot{W}$ : Gaussian noise on  $\mathbb{R}_+ \times \mathbb{R}^d$ , with

$$\mathbb{E} \left[ \dot{W}_t(x) \dot{W}_s(y) \right] = |t - s|^{-\alpha_0} |y - x|^{-\alpha} \quad (1)$$

Remark:

- 1 One can do more general than (1), with a Dalang type condition
- 2 Under (1), we have

$$\dot{W}_t(\cdot) \in \mathcal{B}^{-(\alpha+\varepsilon)/2}$$

# Another point of view on the noise

Noise as a derivative: One has the distributional derivative relation

$$\dot{W}_t(x) = \frac{\partial W}{\partial t \partial x}(t, x),$$

where  $W \equiv$  fractional Brownian sheet

# Covariance in Fourier modes

**Notation for the covariance:** On  $\mathbb{R}_+ \times \mathbb{R}$ , one can write

$$\mathbb{E} \left[ \dot{W}_t(x) \dot{W}_s(y) \right] = \gamma_0(t - s) \gamma_1(y - x)$$

with the following distributional relation:

$$\gamma_j(u, v) = |u - v|^{2H_j - 2}. \quad (2)$$

**Covariance in Fourier modes:**

- The covariance  $\gamma_j$  is given in Fourier mode as

$$\gamma_j(x) = \int_{\mathbb{R}} e^{i\xi x} |\xi_j|^{1-2H_j} d\xi$$

# Equation under consideration

## Equation:

Stochastic heat equation on  $\mathbb{R}^d$ :

$$\partial_t u_t(x) = \frac{1}{2} \Delta u_t(x) + u_t(x) \dot{W}_t(x), \quad (3)$$

with

- $t \geq 0, x \in \mathbb{R}^d$ .
- $\dot{W}$  Gaussian noise such that
  - ▶  $\dot{W}$  white noise or fractional in time
  - ▶  $\dot{W}$  has a certain spatial covariance structure.
- $u_t(x) \dot{W}_t(x)$  differential: Stratonovich or Skorohod sense.

# Motivation: intermittency phenomenon

Equation:  $\partial_t u_t(x) = \frac{1}{2} \Delta u_t(x) + \lambda u_t(x) \dot{W}_t(x)$

Phenomenon: The solution  $u$  concentrates its energy in high peaks.

Characterization: through moments

↪ Easy possible definition of intermittency: for all  $k_1 > k_2 \geq 1$

$$\lim_{t \rightarrow \infty} \frac{\mathbb{E}^{1/k_1} [ |u_t(x)|^{k_1} ]}{\mathbb{E}^{1/k_2} [ |u_t(x)|^{k_2} ]} = \infty.$$

Results:

- White noise in time: Khoshnevisan, Foondun, Conus, Joseph
- Fractional noise in time: Balan-Conus, Hu-Huang-Nualart-T

# Intermittency: illustration (by Daniel Conus)

Simulations: for  $\lambda = 0.1, 0.5, 1$  and  $2$ .

# Model for the noise on $\mathbb{R}_+ \times \mathbb{R}$ (repeated)

Covariance function for  $\dot{W}$ : As before,

$$\mathbb{E} \left[ \dot{W}_t(x) \dot{W}_s(y) \right] = \gamma_0(t-s) \gamma_1(y-x)$$

with the following distributional relation:

$$\gamma_j(u, v) = |u - v|^{2H_j - 2}.$$

# Existence and uniqueness results

Existence-uniqueness in the  $(H_0, H_1)$  plane: according to  $2H_0 + H_1$

# Existence and uniqueness results

Existence-uniqueness in the  $(H_0, H_1)$  plane: according to  $2H_0 + H_1$

# Existence and uniqueness results

Existence-uniqueness in the  $(H_0, H_1)$  plane: according to  $2H_0 + H_1$

# Existence and uniqueness results

Existence-uniqueness in the  $(H_0, H_1)$  plane: according to  $2H_0 + H_1$

# Existence and uniqueness results

Existence-uniqueness in the  $(H_0, H_1)$  plane: according to  $2H_0 + H_1$

# Outline

  - Existence-uniqueness for the heat equation

# A stochastic integral

Heat kernel: Let  $p_t \equiv$  heat kernel for  $\frac{1}{2}\Delta$ ,

$$p_t(x) = \frac{1}{(2\pi t)^{d/2}} \exp\left(-\frac{x^2}{2t}\right)$$

Noise we consider: White in time, colored in space,

$$\mathbb{E} \left[ \dot{W}_t(x) \dot{W}_s(y) \right] = \delta_0(t-s) |y-x|^{-\alpha}$$

A stochastic integral: Set

$$X_t(x) = \int_0^t \int_{\mathbb{R}^d} p_s(x-y) W(ds, dy)$$

# Variance computation

Variance in direct mode: One can prove that

$$\mathbb{E} [|\mathcal{X}_t(x)|^2] = \int_0^t \int_{\mathbb{R}^d \times \mathbb{R}^d} p_s(x - y_1) |y_1 - y_2|^{-\alpha} p_s(x - y_2) ds dy_1 dy_2$$

Variance in Fourier mode: We also have

$$\mathbb{E} [|\mathcal{X}_t(x)|^2] = \int_0^t \int_{\mathbb{R}^d} |\mathcal{F} p_s(\xi)|^2 |\xi|^{d+\alpha} ds d\xi$$

↔ Much easier to handle!

# Long term project

## Main question:

- Do we observe a big difference in the previous exponents  
↔ under geometric settings?

## Settings of interest:

- Sub-Riemannian manifolds
- On Heisenberg groups: use of Fourier
- Fractals

## Related models:

- Polymers
- KPZ equation

# Group structure

Symplectic form on  $\mathbb{R}^{2n}$ :

$$\omega((x, y), (x', y')) = \sum_{i=1}^n x'_i y_i - x_i y'_i$$

Heisenberg group  $\mathbf{H}^n$ : Seen as  $\mathbb{R}^{2n+1}$  equipped with

$$(x, y, z) \star (x', y', z') := \left( x + x', y + y', z + z' + 2\omega((x, y), (x', y')) \right)$$

# Sub-Riemannian structure

Invariant vector fields:

At  $p = (x, y, z)$  and for  $i = 1, \dots, n$ , given as

$$X_i(p) = \partial_{x_i} + 2y_i\partial_z, \quad Y_i(p) = \partial_{y_i} - 2x_i\partial_z, \quad Z(p) = \partial_z.$$

Then  $X_i, Y_i$  are the **horizontal vector fields**.

**Horizontal sub-Laplacian:** Defined by

$$\Delta = \sum_{i=1}^n X_i^2 + Y_i^2.$$

# Horizontal tangent planes in $\mathbf{H}^n$

$$X_i(p) = \partial_{x_i} + 2y_i\partial_z, \quad Y_i(p) = \partial_{y_i} - 2x_i\partial_z.$$

# Distance

Carnot-Carathéodory distance:

$$d_{cc}(p_1, p_2) := \inf \left\{ \int_0^1 |\dot{\gamma}(t)|_{\mathcal{H}} dt ; \right. \\ \left. \gamma : [0, 1] \rightarrow \mathbf{H}^n \text{ is horizontal, } \gamma(0) = p_1, \gamma(1) = p_2 \right\}$$

Bounds on cc-distance:

$$C_1(\sqrt{|(x, y)|^2 + |z|^{\frac{1}{2}}}) \leq d_{cc}(e, q) \leq C_2(\sqrt{|(x, y)|^2 + |z|^{\frac{1}{2}}})$$

# Unit sphere in $\mathbf{H}^n$

# Heat kernel

**Definition:** Solution of

$$\partial_t p_t(q) = \frac{1}{2} \Delta p_t(q), \quad p_0(q) = \delta_e(q)$$

**Gaussian type bounds:** We have

$$\frac{c_1}{t^{n+1}} \exp\left(-\frac{c_2}{t} d_{cc}(e, q)^2\right) \leq p_t(q) \leq \frac{c_3}{t^{n+1}} \exp\left(-\frac{c_4}{t} d_{cc}(e, q)^2\right)$$

**Remark:** The heat kernel is more singular

↔ Than the heat kernel in  $\mathbb{R}^{2n+1}$

  - Existence-uniqueness for the heat equation

# Usual Fourier transform

A unitary group representation:

For  $q = (x, y, z) \in \mathbf{H}^n$ ,  $\lambda \in \mathbb{R}$  and  $u \in L^2(\mathbb{R}^n)$  we set

$$U_q^\lambda u(\xi) = e^{-i\lambda(z+2x \cdot (\xi-y))} u(\xi - 2y), \quad \xi \in \mathbb{R}^n$$

Fourier transform: For  $f \in L^1(\mathbf{H}^n)$ , operator valued,

$$\mathcal{F}(f)(\lambda) = \int_{\mathbf{H}^n} f(q) U_q^\lambda d\mu(q).$$

Relation with Laplacian: We have

$$\mathcal{F}(\Delta f)(\lambda) = 4 \mathcal{F}(f)(\lambda) \circ \Delta_{\text{osc}}^\lambda$$

with

$$\Delta_{\text{osc}}^\lambda u(x) = \sum_{j=1}^n \partial_j^2 u(x) - \lambda^2 |x|^2 u(x)$$

# Projective version of Fourier

**Hermite functions:** Onb for  $-\Delta_{\text{osc}}^1$ , defined for  $k \in \mathbb{N}^n$  by

$$-\Delta_{\text{osc}}^1 \Phi_k = (2|k| + n) \Phi_k$$

**Rescaled Hermite functions:**

$$\Phi_k^\lambda(x) = |\lambda|^{n/4} \Phi_k\left(\sqrt{|\lambda|}x\right)$$

**Projective Fourier:** For  $(m, \ell, \lambda) \in \mathbb{N}^n \times \mathbb{N}^n \times \mathbb{R}^*$ , we set

$$\hat{f}(m, \ell, \lambda) = \langle \mathcal{F}(f)(\lambda) \Phi_m^\lambda, \Phi_\ell^\lambda \rangle_{L^2(\mathbb{R}^n)}$$

# Properties of the projective version

Plancherel identity: We have

$$\int_{\mathbf{H}^n} |f(q)|^2 dq = \frac{2^{n-1}}{\pi^{n+1}} \sum_{m, \ell \in \mathbb{N}^n} \int_{-\infty}^{+\infty} |\hat{f}(m, \ell, \lambda)|^2 |\lambda|^n d\lambda$$

Fourier and Laplace: For a smooth enough  $f$ ,

$$\widehat{\Delta} f(m, \ell, \lambda) = -4 |\lambda| (2|m| + n) \hat{f}(m, \ell, \lambda)$$

Powers of Laplace: For  $\alpha > 0$ ,

$$(-\widehat{\Delta})^{-\alpha} f(m, \ell, \lambda) = 4^{-\alpha} |\lambda|^{-\alpha} (2|m| + n)^{-\alpha} \hat{f}(m, \ell, \lambda)$$

# A class of Gaussian noises

**Test function:** For  $\alpha \geq 0$  and  $\varphi$  smooth, set

$$\mathbf{W}_\alpha(\varphi) = \int_{\mathbb{R}_+} \int_{\mathbf{H}^n} \varphi(t, q) \mathbf{W}_\alpha(dt, dq)$$

**Covariance:** For 2 test functions  $\varphi, \psi$ ,

$$\mathbb{E} [\mathbf{W}_\alpha(\varphi) \mathbf{W}_\alpha(\psi)] = \langle (-\Delta)^{-\alpha} \varphi, (-\Delta)^{-\alpha} \psi \rangle_{L^2(\mathbb{R}_+ \times \mathbf{H}^n)}$$

# Properties of the Gaussian noise

Relation with white noise: One can write

$$\mathbf{W}_\alpha = (-\Delta)^{-\alpha} \mathbf{W}, \quad \text{with } \mathbf{W} \equiv \text{space-time white noise on } \mathbf{H}^n$$

Inequality for the covariance: For positive test functions  $\varphi, \psi$ ,

$$\mathbb{E} [\mathbf{W}_\alpha(\varphi) \mathbf{W}_\alpha(\psi)] \asymp \int_{\mathbb{R}_+} \int_{(\mathbf{H}^n)^2} \frac{\varphi(t, q_1) \psi(t, q_2)}{d_{cc}(q_1, q_2)^{2n+2-4\alpha}} dt d\mu(q_1) d\mu(q_2)$$

# Existence-uniqueness

## Theorem 3.

Consider

- Noise  $\mathbf{W}_\alpha$  as in previous slide
- Stochastic heat equation on  $\mathbf{H}^n$ :

$$\partial_t u_t(q) = \frac{1}{2} \Delta u_t(q) + u_t(x) \dot{W}_t(q),$$

interpreted in the Itô sense.

Then a necessary and sufficient condition

↪ to have **existence and uniqueness** is

$$\alpha > \frac{n}{2}$$

# Comparison with $\mathbb{R}^d$

**Bessel noises:** Noises on  $\mathbb{R}^d$  with covariance

$$\mathbb{E} [\mathbf{W}_\alpha(\varphi)\mathbf{W}_\alpha(\psi)] = \langle (\text{Id} - \Delta)^{-\alpha}\varphi, (\text{Id} - \Delta)^{-\alpha}\psi \rangle_{L^2(\mathbb{R}_+ \times \mathbb{R}^d)}$$

**Condition in  $\mathbb{R}^d$ :** In order to solve SHE,

$$\alpha > \frac{d}{4} - \frac{1}{2}$$

**Condition in  $\mathbf{H}^n$ :** The condition  $\alpha > n/2$  can be read as

$$\alpha > \frac{Q}{4} - \frac{1}{2}, \quad \text{with} \quad Q = 2n + 2 = \text{Effective dimension}$$

# The basic identity in $\mathbf{H}^n$

Stochastic convolution: Consider the process

$$X_t \equiv \int_0^t \int_{\mathbf{H}^n} p_{t-s}(q) \mathbf{W}_\alpha(ds, dq)$$

Variance in Fourier mode:

$$\mathbb{E} [X_t^2] = \int_{[0,t]} ds \int_{\mathbb{R}} |\lambda|^n \sum_{m \in \mathbb{N}^n} |\lambda|^{-2\alpha} (2|m| + n)^{-2\alpha} e^{-8s|\lambda|(2|m|+n)} d\lambda$$

Lower bound: We have

$$\mathbb{E} [X_t^2] \gtrsim \int_{[0,t]} ds \int_{\mathbb{R}} |\lambda|^{n-2\alpha} e^{-8ns|\lambda|} d\lambda$$

This is finite for  $\alpha \in (\frac{n}{2}, \frac{n+1}{2})$
