

## Meeting 11.2: Topological quantum computing, III

I. Quantum circuits inside extended TQFTs, *continued*

II. Which TQFTs are BQP-universal?

Last time: can try to use quantum representation of mapping class group of (closed) surface determined by a unitary TQFT to process quantum information.

Problem: don't have any clear way to decompose Hilbert space  $\mathcal{Z}(S)$  into tensor product of subspaces.

So, unclear how to encode quantum circuits...

One (unhelpful) idea: use disconnected surfaces?

Quantum representation won't generate entanglement...

$$\mathcal{Z}(\text{two holes}) \otimes \mathcal{Z}(\text{two holes}) \otimes \mathcal{Z}(\text{two holes})$$

Solution: use extended TQFT!

EXTENDED TQFTs have even nicer cut and paste properties

In addition to computing  $Z(M^3)$  by cutting  $M^3$  along a surface, we can cut surfaces along curves to compute their state spaces.

To make precise, <sup>we will assume</sup> extended TQFTs come equipped with a finite set of "colors"  $C = \{1, 2, \dots, r\}$ .

We then define the  $C$ -colored, once extended  $(2+1)$ -dimensional cobordism category  $C\text{-Cob}(2+1)$ .

Contains  $\text{Cob}(2+1)$  as a subcategory.

Note: what follows is imprecise and incorrect, probably. Why? Don't want to define extended TQFT or modular tensor category in full detail...

$C\text{-Cob}(2+1)$  includes new objects:

Surfaces with (oriented ....) boundary and oriented marked points, with all boundary components and marked points

Objects are  
" $C$ -colored surfaces  
w/ marked points"

$\Gamma = 10$ , i.e.

$$C = \{1, 2, 3, \dots, 10\}$$

# And new morphisms:

3-manifolds with properly embedded,  $\mathbb{C}$ -colored trivalent, oriented ribbon graphs

Technically also need to color trivalent vertices by another set...

(Need to allow 3-manifolds with "corners!")

Note:  
Morphisms only compose when boundary colorings are compatible

Ribbon graph?

Normal graph

Ribbon graph

Why? Up to isotopy rel boundary

#1

$\approx$   
=

"ribbon twist  
relation"

As for usual/unextended TQFTs, an extended  $\checkmark$  TQFT is  
a  $\mathcal{Q}$ -functor  
unitary

$$Z: \mathcal{C}\text{-Cob}(2+1) \longrightarrow \text{Hilb.}$$

In addition to all the axioms for Atiyah TQFT, an extended TQFT includes axioms that require Functoriality w.r.t. cutting/pasting of  $\mathbb{C}$ -colored surfaces. Most important for our purposes:

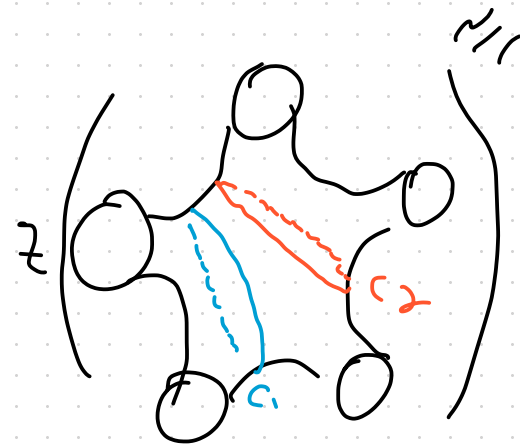

matrix  $\otimes$ -isomorphism

$$Z \left( \text{Diagram 1} \right) \cong \bigoplus_{c \in \mathbb{C}} Z \left( \text{Diagram 2} \right) \otimes Z \left( \text{Diagram 3} \right)$$

$$Z \left( \text{Diagram 4} \right) \cong \bigoplus_{c \in \mathbb{C}} Z \left( \text{Diagram 5} \right)$$

GLUING AXIOM

Cutting/pasting "commute":

cut along  $c_1$  then cut along  $c_2$

Commutative!

Gluing axiom allows to specify elements of  $\mathcal{Z}(S)$  by labelling a complete disk system of  $S$  with orientations and elements of  $\mathbb{C}$

Note, e.g.

$Z$  (  ) is 1-dimensional.

Why?

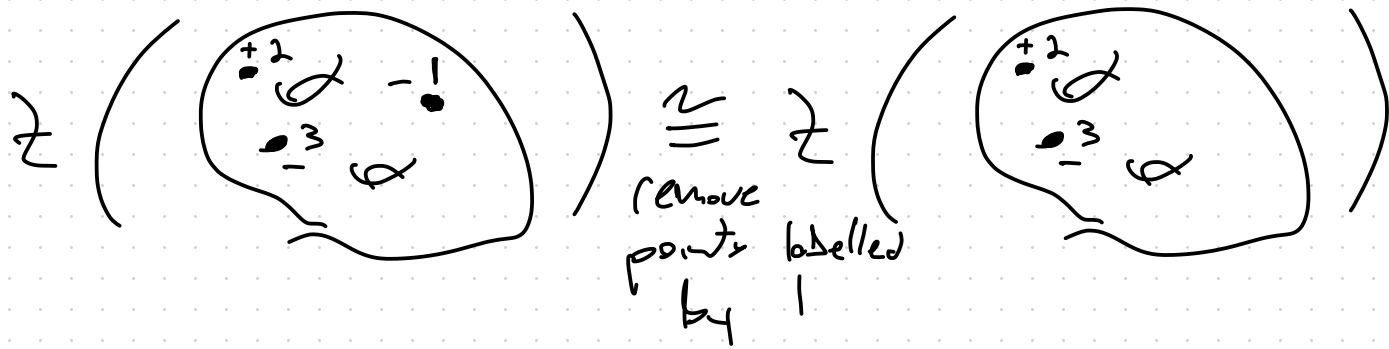

This yields a  $C$ -colored surface  
homeomorphic to  $S$ .

Then

$$\mathbb{Z}(S) \cong \mathbb{Z}(S) \otimes \mathbb{Z}(\text{cylinder})$$

must be 1-dimensional!

Another axiom: the color 1 is special

Gluing axioms allow us to build models of circuits. Here's one based on closed surfaces.

Given  $Z$  and  $S$ , we "localize"  $^n$  quantum rep of  $MCG(S)$  along the  $S_i^n$ 's.

Vier gluing state in  $Z(S)$  lies in a subspace of the form

$$Z(S_1, c_1) \otimes Z(S_2, c_2) \otimes \dots \otimes Z(S_n, c_n) \otimes Z(T, c_1, c_2, \dots, c_n)$$

where

$$\mathcal{Z}(S, c_i) = \mathcal{Z}$$

$$\mathcal{Z}(T, c_1, \dots, c_n) = \mathcal{Z}$$
A hand-drawn diagram of a genus  $g$  surface, represented as a horizontal cylinder with  $g$  handles. The handles are indicated by horizontal ellipses in the center.  $n$  blue loops, labeled  $c_1, c_2, \dots, c_n$ , are drawn around the handles. Each loop  $c_i$  is a small circle with an arrow pointing to the right.

$Z(S)$  is spanned by subspaces of form

$$Z(S_1, c_1) \otimes Z(S_2, c_2) \otimes \cdots \otimes Z(S_n, c_n) \otimes Z(T, c_1, c_2, \dots, c_n)$$

as we vary  $c_i$ 's in  $C = \{1, 2, \dots, r\}$ .

## Setting up circuits

Various ways to do it...

Let's fix one subspace, i.e. this one:

$$\mathbb{Z}(S_1, c) \otimes \mathbb{Z}(S_2, c) \otimes \cdots \otimes \mathbb{Z}(S_n, c) \otimes \mathbb{Z}(T, c_1, \dots, c_r)$$

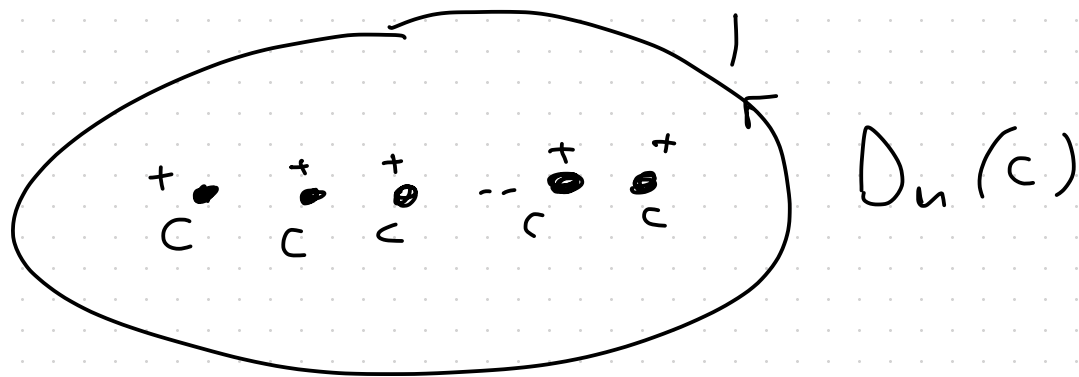

Look at  $\Gamma = \Gamma(c) \subseteq \text{MCG}(S)$ , the subgroup that preserves this subspace.

Def'n: twists along orange curves generate  $MCG(S)$

Another approach: use braids

Consider disk  $D_n(c)$   $n$  points all colored by  $c$   
and boundary colored by  $1$ :

$B_n$  acts on  $\mathcal{Z}(D_n(c))$

Fix  $k$ , and consider  $n$  copies of  $D_k(c)$   
glued together along boundary

eg:  $k=3$

$$\mathbb{B}_{k_n} \supset D_{k_n}(c).$$

$\mathcal{Z}(D_{k_h}(c))$  contains  $\otimes$ 's  
of  $\mathcal{Z}(D_{k_h}(c))$  --

$$\mathcal{Z}(D_k(c)) \otimes \dots \otimes \mathcal{Z}(D_k(c)) \subseteq \mathcal{Z}(D_{k_h}(c)).$$

Can use subgroup of  $B_{k_h}$  that preserves  
this subspace to build circuits.

What circuits can we simulate?

## II. Which TQFTs are BQP-universal?

(Should assume TQFT is unitary and extended.)

Interesting question in all dimensions.

Has received most attention in dimension  $2+1$ .

Why?

- In dimensions  $\leq 3$ , too weak....
- In dimensions  $> 3$ , poorly understood. Expected to be too weak if "fully extended"...
- In dimension  $3$ , extended TQFTs all come from modular tensor categories via Reshetikhin-Turaev construction. "Combinatorial"-ish

Key question: given  $\mathcal{Z}$ , are there colored surfaces  $S$  whose quantum representations are dense in  $PU(\mathcal{Z}(S))$ ?

If answer is yes, you can simulate / approximate (via Solovay-Kitaev and additional tricks) arbitrary quantum circuits.
