

Analysis of the Scattering by an Unbounded Rough Surface

Peijun Li* and Jie Shen†

Abstract

This paper is concerned with the mathematical analysis of the solution for the wave propagation from the scattering by an unbounded penetrable rough surface. Throughout the wavenumber is assumed to have a nonzero imaginary part which accounts for the energy absorption. The scattering problem is modeled as a boundary value problem governed by the Helmholtz equation with transparent boundary conditions proposed on plane surfaces confining the scattering surface. The existence and uniqueness of the weak solution for the model problem are established by using a variational approach. Furthermore, the scattering problem is investigated for the case when the scattering profile is a sufficiently small and smooth deformation of a plane surface. Under this assumption, the problem is equivalently formulated into a set of two-point boundary value problems in the frequency domain, and the analytical solution, in the form of an infinite series, is deduced by using a boundary perturbation technique combined with the transformed field expansion approach.

Key words. Helmholtz equation, variational formulation, rough surface scattering, boundary perturbation method, transformed field expansion

1 Introduction

This paper is concerned with the mathematical analysis of the solution for an acoustic wave scattering problem by an unbounded penetrable rough surface. An unbounded rough surface is a non-local perturbation of an infinite plane surface such that the whole surface lies within a finite distance of the original plane. The problem studied in this work falls in the class of rough surface scattering problems, which arise from various applications in industry and military, such as modeling acoustic and electromagnetic wave propagation over outdoor ground and sea surfaces, optical scattering from the surface of materials in near-field optics or nano-optics, detection of underwater mines, especially those buried in soft sediments. These problems have received much attention and been intensively examined by researchers in the engineering community. A considerable amount of information is available concerning their solutions via both rigorous methods of computation and approximate, asymptotic, or statistical methods, e.g., the reviews and monographs by Ogilvy [38], Voronovich [42], Saillard and Sentenac [40], Warnick and Chew [43], DeSanto [22], Elfouhaily and Guerin [26], and references cited therein.

We study the acoustic wave propagation problem of the Helmholtz equation with an unbounded penetrable scattering surface. Specifically, we consider the scattering of a time-harmonic wave field, generated from a point source, incident on an infinite rough surface from the top, where the spaces above and below the scattering surface are filled with some fixed materials, respectively. The unbounded rough surface scattering problem is challenging due to three major reasons: (i) an appropriate radiation condition is required as a part of the boundary value problem, since the usual Sommerfeld radiation condition is no longer valid due to the unboundedness of the rough surface; (ii) lack of compactness of the solution functional space due to the unboundedness of the domain; (iii) computationally, a usual approach is to truncate the open domain into a bounded domain, and thus transparent boundary conditions have to be imposed on the boundary of the truncated bounded domain so that no artificial wave reflection occurs. Despite the large amount of work done so far for the unbounded rough surface scattering problems, the above issues still cannot be considered completely solved, particularly for the transparent boundary conditions from the computational point of view, and remain to be the subject matter of much ongoing research.

This paper consists of two major parts. The first part is concerned with the existence and uniqueness of the solution for a general scattering surface. The second part deals with the derivation of an analytical solution for a special class of scattering surfaces: sufficiently small and smooth deformation of plane surface.

In the first part, the scattering problem is modeled as a boundary value problem for acoustic wave propagation governed by the two-dimensional Helmholtz equation with transparent boundary conditions proposed on plane surfaces confining the scattering surface. Since the usual Sommerfeld radiation condition is not valid, the transparent boundary conditions are derived from the new radiation condition: the total field is consisted of bounded outgoing waves above and below the scattering surface, plus the incident field above the scattering surface. This radiation condition is equivalent to the upward propagating radiation condition proposed for a two-dimensional rough surface scattering problems by Chandler-Wilde and Zhang [18], and has recently been analyzed carefully by Arens and Hohage [5]. The existence and uniqueness of the weak solution for the model problem are established by using a variational approach. The method enjoys a great generality in the sense that it allows very general surface structures. Throughout we restrict to the case of lossy medium, where the wavenumber is assumed to have a nonzero imaginary part accounting for the energy absorption. We refer to Ritterbusch [39], Chandler-Wilde and Elschner [13] for related scattering problems where weighted Sobolev spaces are studied for unbounded domains.

The rough surface scattering problems for the Helmholtz equation have been recently studied by Chandler-Wilde and Monk [15], Chandler-Wilde et al. [16], and Lechleiter and Ritterbusch [30], who considered variational approaches to solve a two- or three-dimensional rough surface scattering problem which models the time-harmonic acoustic wave scattering by a layer of homogeneous or inhomogeneous medium above a sound soft rough surface. We refer to Li et al. [32] of the scattering problem for the vector form of Maxwell's equations with dielectric surfaces, which models the time-harmonic electromagnetic wave by three layers of inhomogeneous medium with two infinite rough surfaces. In addition, the two-dimensional scalar model problem has been considered by integral equation methods in two cases. The first case assumes that the medium is homogeneous and the surface is the graph of a sufficiently smooth bounded function, when the boundary integral equation methods are applicable, e.g., Chandler-Wilde et al. [14, 17], Zhang and Chandler-Wilde [45, 46], and DeSanto and Martin [23–25]. The second case studied is that the surface is a straight line, e.g., Chandler-Wilde and Zhang [19] and Li [31].

In the second part, we derive an analytical solution for the scattering problem based on a boundary perturbation technique combined with the transformed field expansion, under the assumption that scattering rough surface is a sufficiently small and smooth deformation of a plane

surface. By the transformed field expansion, the original problem with complex scattering surface is converted into a set of recursive transmission problems with a flat interface. Furthermore, the nonlocal transparent boundary conditions become local boundary condition in the frequency domain. Therefore, we can reduce the two-dimensional problem into a sequence of one-dimensional two-point boundary value problem with exact local boundary conditions. This approach not only leads to the availability of analytical solution in the form of an infinite series, but also an efficient and robust computational method (cf. [29]).

For boundary perturbation methods, we refer to a series of papers by Bruno and Reitich [8–12], Nicholls and Reitich [35], and references cited therein, for the rigorous mathematical and numerical analysis for solving some diffraction grating and obstacle scattering problems. An improved boundary perturbation algorithm, termed as transformed field expansion, was proposed by Nicholls and Reitich [36], where a change of variables was done first to flatten the shape of the scattering surface and then followed by the boundary perturbation technique. The transformed field expansion method was shown to be accurate, stable, and robust even at high order, see, e.g., Nicholls and Shen [37] and Fang et al. [27] for solving the two- and three-dimensional bounded obstacle scattering problems.

We also point out that some related work for the scattering of acoustic and electromagnetic waves in a grating (periodic surface) structure (diffractive optics) and in a cavity (local perturbation of a plane surface). They have been studied extensively by either integral equation methods or variational approaches (cf. Bao [6, 7], Ammari et al. [3, 4], Van and Wood [41], Woo [44], and reference therein). More recently, existence of the solution to the acoustic and electromagnetic scattering problem in infinite periodic surface perturbed by a single inhomogeneous object placed inside the periodic structure are established via the integral equation method by Ammari and Bao [1, 2]. One may consult Colton and Kress [20, 21], Nédélec [34], and Monk [33] for extensive accounts of the integral equation methods and finite element methods for acoustic and electromagnetic scattering problems.

The outline of this paper is as follows. In Section 2, the model problem is introduced and some regularity properties of the trace operator are discussed. Section 3 is devoted to the derivation of the transparent boundary condition. Some estimates of the capacity operator are introduced. A variational formulation for the unbounded rough surface acoustic scattering problem is introduced by using the transparent boundary condition. The existence and uniqueness of the weak solution for the variational problem are established. Based on the boundary perturbation technique combined with the transformed field expansion, an analytical solution is derived in Section 4. The paper is concluded with some general remarks and directions for future research in Section 5.

2 A model problem

In this section, we shall introduce a mathematical model and define some notation for the scattering problem by an unbounded rough surface. Let the scattering surface be described by the curve $S = \{(x, y) : y = f(x), x \in \mathbb{R}\}$ with a bounded and Lipschitz continuous function f , as seen in Figure 1. The scattering surface S is embedded in the strip

$$\Omega = \{(x, y) \in \mathbb{R}^2 : y_- < y < y_+\} = \mathbb{R} \times (y_-, y_+),$$

where y_- and y_+ are two constants. Let $\Omega_f^+ = \{(x, y) : y > f(x)\}$ and $\Omega_f^- = \{(x, y) : y < f(x)\}$ be filled with materials whose wavenumbers are constants κ_+ and κ_- , respectively. In fact, the wavenumber satisfies $\kappa_{\pm}^2 = \omega^2 \mu \varepsilon_{\pm}$, where ω is the angular frequency, μ is the magnetic permeability which is assumed to be a constant everywhere, and ε_{\pm} is the electric permittivity in Ω_f^{\pm} . In this

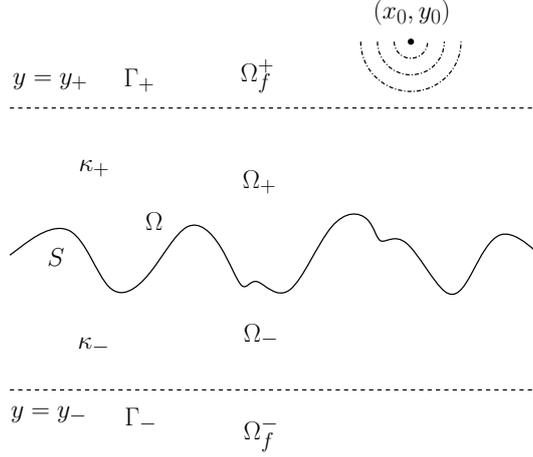

Figure 1: Problem geometry. A wave from the point source at (x_0, y_0) is incident on the scattering surface S from the top. The spaces Ω_f^+ (above S) and Ω_f^- (below S) are filled with materials whose wavenumbers are constants κ_+ and κ_- , respectively.

work, the wavenumber κ_{\pm} is assumed to be a fixed complex number with

$$\alpha > \operatorname{Re}\kappa_{\pm}^2 > 0 \quad \text{and} \quad \operatorname{Im}\kappa_{\pm}^2 > \beta > 0. \quad (2.1)$$

The condition $\operatorname{Im}\kappa_{\pm}^2 > 0$ accounts for energy absorption. Denote by $\Gamma_+ = \{y = y_+\}$ and $\Gamma_- = \{y = y_-\}$ the top and bottom boundaries of the domain Ω .

Suppose that a wave generated from a point source is incident on S from the top. Explicitly, the point incident field is taken as the fundamental solution of the Helmholtz equation in Ω_+ , i.e.,

$$u^{\text{inc}}(x, y; x_0, y_0) = \frac{i}{4} H_0^{(1)}(\kappa_+ |(x, y) - (x_0, y_0)|), \quad (2.2)$$

where $H_0^{(1)}$ is the Hankel function of first kind with order zero, $\mathbf{x} = (x, y)$ is the observation point, and $\mathbf{x}_0 = (x_0, y_0)$ is a given source point in Ω_+ . Clearly the incident field satisfies the two dimensional Helmholtz equation:

$$\Delta u^{\text{inc}}(\mathbf{x}) + \kappa_+^2 u^{\text{inc}}(\mathbf{x}) = -\delta(\mathbf{x} - \mathbf{x}_0) \quad \text{in } \mathbb{R}^2,$$

where δ is the Dirac delta function.

The scattering of time harmonic electromagnetic waves in the transverse electric case can also be modeled by the two dimensional Helmholtz equation:

$$\Delta u(\mathbf{x}) + \kappa^2 u(\mathbf{x}) = -\delta(\mathbf{x} - \mathbf{x}_0) \quad \text{in } \mathbb{R}^2, \quad (2.3)$$

where the wavenumber

$$\kappa = \begin{cases} \kappa_+ & \text{in } \Omega_f^+, \\ \kappa_- & \text{in } \Omega_f^-. \end{cases} \quad (2.4)$$

Due to the unbounded scattering surface, the usual Sommerfeld radiation condition is no longer valid. The radiation condition that we impose is the boundedness of u as y tends to infinity. More precisely, we insist that u is composed of bounded outgoing waves in Ω_+ and Ω_- plus the incident wave u^{inc} in Ω_+ .

To describe the boundary value problem and derive its variational formulation, we need to introduce some functional space notations. For $u \in L^2(\Gamma_{\pm})$, which is identified with $L^2(\mathbb{R})$, we denote by \hat{u} the Fourier transform of u defined by

$$\hat{u}(\xi) = \int_{\mathbb{R}} u(x)e^{ix\xi} dx.$$

Using Fourier modes, the norm on the space $L^2(\Gamma_{\pm})$ can be characterized by

$$\| u \|_{L^2(\Gamma_{\pm})} = \| u \|_{L^2(\mathbb{R})} = \left[\int_{\mathbb{R}} |u|^2 dx \right]^{1/2} = \left[\int_{\mathbb{R}} |\hat{u}|^2 d\xi \right]^{1/2}.$$

We denote by $C_x^\infty(\Omega)$ the linear space of infinitely differential functions with compact support with respect to the variable x on Ω . Denote by $L^2(\Omega)$ the space of complex square integrable functions on Ω with the norm

$$\| u \|_{L^2(\Omega)} = \left[\int_{y_-}^{y_+} \int_{\mathbb{R}} |u(x, y)|^2 dx dy \right]^{1/2} = \left[\int_{y_-}^{y_+} \int_{\mathbb{R}} |\hat{u}(\xi, y)|^2 d\xi dy \right]^{1/2}.$$

Denote the Sobolev space: $H^1(\Omega) = \{D^s u \in L^2(\Omega) \text{ for all } |s| \leq 1\}$. A simple calculation yields an explicit characterization of the norm in $H^1(\Omega)$ via Fourier coefficient:

$$\| u \|_{H^1(\Omega)}^2 = \int_{y_-}^{y_+} \int_{\mathbb{R}} [(1 + |\xi|^2) |\hat{u}(\xi, y)|^2 + |\hat{u}'(\xi, y)|^2] d\xi dy, \quad (2.5)$$

where $\hat{u}'(\xi, y) = \partial_y \hat{u}(\xi, y)$. In addition, to describe the boundary operator and transparent boundary condition in the formulation of the boundary value problem, we define the trace functional space

$$H^s(\Gamma_{\pm}) = \{u \in L^2(\Gamma_{\pm}) : \int_{\mathbb{R}} (1 + |\xi|^2)^s |\hat{u}|^2 d\xi < \infty\},$$

whose norm is characterized by

$$\| u \|_{H^s(\Gamma_{\pm})}^2 = \int_{\mathbb{R}} (1 + |\xi|^2)^s |\hat{u}|^2 d\xi. \quad (2.6)$$

It is clear that the dual space associated with $H^s(\Gamma_{\pm})$ is the space $H^{-s}(\Gamma_{\pm})$. In particular, it holds the following duality lemma.

Lemma 2.1. *The spaces $H^{1/2}(\Gamma_{\pm})$ and $H^{-1/2}(\Gamma_{\pm})$ are mutually adjoint with respect to the scalar product in $L^2(\Gamma_{\pm})$.*

The following lemma is concerned with the density of $C_x^\infty(\Omega)$. This is important, particularly for our case of unbounded slab Ω , since it allows us to prove results for smooth functions with compact support and extend them by limiting argument to more general functions.

Lemma 2.2. *$C_x^\infty(\Omega)$ is dense in $H^1(\Omega)$.*

Proof. Noting that $C_0^\infty(\mathbb{R}^2)$ is dense in $H^1(\mathbb{R}^2)$, we have $C_0^\infty(\mathbb{R}^2)|_{\Omega}$ is dense in $H^1(\mathbb{R}^2)|_{\Omega}$. From the Sobolev extension theorem, $H^1(\mathbb{R}^2)|_{\Omega} = H^1(\Omega)$. Therefore $C_x^\infty(\Omega) \supseteq C_0^\infty(\mathbb{R}^2)|_{\Omega}$ is dense in $H^1(\Omega)$. \square

To simplify proofs, we shall employ positive constants C and C_i as generic constants whose precise values are not required and may change line by line but should be always be clear from the context.

The following lemma shows that the space $H^{1/2}(\Gamma_{\pm})$ and $H^{-1/2}(\Gamma_{\pm})$ are mutually adjoint under the dual pairing $\langle \cdot, \cdot \rangle_{\Gamma_{\pm}}$ defined by

$$\langle u, v \rangle_{\Gamma_{\pm}} = \int_{\mathbb{R}} \hat{u} \bar{\hat{v}} d\xi. \quad (2.7)$$

Note that, from the Parseval formula, the dual pairing $\langle u, v \rangle_{\Gamma_{\pm}}$ is the $L^2(\Gamma_{\pm})$ inner product between u and v if $u, v \in L^2(\Gamma_{\pm})$.

The following trace regularity result in $H^{1/2}(\Gamma_{\pm})$ is useful in subsequent analysis.

Lemma 2.3. *Let $\gamma_0 = \sqrt{1 + (y_+ - y_-)^{-1}}$. It holds the estimate*

$$\| u \|_{H^{1/2}(\Gamma_{\pm})} \leq \gamma_0 \| u \|_{H^1(\Omega)}$$

for all $u \in H^1(\Omega)$.

Proof. First we have

$$\begin{aligned} (y_+ - y_-) |\zeta(y_{\pm})|^2 &= \int_{y_-}^{y_+} |\zeta(y)|^2 dy + \int_{y_-}^{y_+} \int_y^{y_{\pm}} \frac{d}{dt} |\zeta(t)|^2 dt dy \\ &\leq \int_{y_-}^{y_+} |\zeta(y)|^2 dy + (y_+ - y_-) \int_{y_-}^{y_+} 2|\zeta(y)| |\zeta'(y)| dy, \end{aligned}$$

which implies by the Cauchy–Schwarz inequality that

$$(1 + |\xi|^2)^{1/2} |\zeta(y_{\pm})|^2 \leq \gamma_0^2 (1 + |\xi|^2) \int_{y_-}^{y_+} |\zeta(y)|^2 dy + \int_{y_-}^{y_+} |\zeta'(y)|^2 dy. \quad (2.8)$$

Given u in $H^1(\Omega)$, it follows from the definition (2.6) that

$$\| u \|_{H^{1/2}(\Gamma_{\pm})}^2 = \int_{\mathbb{R}} (1 + |\xi|^2)^{1/2} |\hat{u}(\xi, y_{\pm})|^2 d\xi.$$

Using (2.8) we obtain

$$\begin{aligned} (1 + |\xi|^2)^{1/2} |\hat{u}(\xi, y_{\pm})|^2 &\leq \gamma_0^2 (1 + |\xi|^2) \int_{y_-}^{y_+} |\hat{u}(\xi, y)|^2 dy + \int_{y_-}^{y_+} |\hat{u}'(\xi, y)|^2 dy \\ &\leq \gamma_0^2 \int_{y_-}^{y_+} [(1 + |\xi|^2) |\hat{u}(\xi, y)|^2 + |\hat{u}'(\xi, y)|^2] dy. \end{aligned}$$

The proof is complete by combining the above estimate and noting the definition of $\|u\|_{H^{1/2}(\Gamma_{\pm})}$ in (2.5). \square

3 Variational problem

In this section, we shall derive the boundary operators, which map the electric fields to their normal derivatives, introduce the transparent boundary conditions on the artificial boundaries Γ_{\pm} , and present a variational formulation for the scattering problem. The existence and uniqueness for the weak solution of the model problem will then be established.

3.1 Transparent boundary condition

We wish to reduce the problem (2.3) in \mathbb{R}^2 to the domain Ω . The radiation condition for the scattering problem insists that the total field u is composed of bounded outgoing waves in Ω_+ and Ω_- , plus the incident field u^{inc} in Ω_+ . Since the derivative of the transparent boundary conditions on Γ_+ and Γ_- are parallel, we will only show how to deduce the transparent boundary condition on Γ_+ , and state the corresponding transparent boundary condition on Γ_- without derivation.

Observe that the medium is homogeneous above Γ_+ . The scattered field $u^s = u - u^{\text{inc}}$ satisfies

$$\Delta u^s + \kappa_+^2 u^s = 0 \quad \text{above } \Gamma_+. \quad (3.1)$$

By taking the Fourier transform of (3.1) with respect to x , we have

$$\frac{\partial^2 \hat{u}^s(\xi, y)}{\partial y^2} + (\kappa_+^2 - \xi^2) \hat{u}^s(\xi, y) = 0 \quad \text{for } y > y_+. \quad (3.2)$$

Since only bounded outgoing wave is allowed for the solution of (3.2), we deduce that

$$\hat{u}^s(\xi, y) = \hat{u}^s(\xi, y_+) e^{i\beta_+(y-y_+)}, \quad (3.3)$$

where

$$\beta_+^2(\xi) = \kappa_+^2 - |\xi|^2 \quad \text{with } \text{Im}\beta_+(\xi) > 0.$$

Taking the inverse Fourier transform of $\hat{u}^s(\xi, y)$, we find from (3.3) that

$$u^s(x, y) = \int_{\mathbb{R}} \hat{u}^s(\xi, y_+) e^{i\beta_+(y-y_+)} e^{i\xi x} d\xi.$$

Taking the normal derivative, which is the partial derivative with respect to y on Γ_+ , and evaluating at y_+ yield

$$\partial_{\mathbf{n}_+} u^s(x, y) \Big|_{y=y_+} = \int_{\mathbb{R}} i\beta_+ \hat{u}^s(\xi, y_+) e^{i\xi x} d\xi, \quad (3.4)$$

where \mathbf{n}_+ is the unit outward normal on Γ_+ , i.e., $\mathbf{n}_+ = (0, 1)^\top$.

For any given u on Γ_+ , define the boundary operator T_+ :

$$T_+ u = \int_{\mathbb{R}} i\beta_+ \hat{u}(\xi, y_+) e^{i\xi x} d\xi,$$

which leads to a transparent boundary condition on Γ_+ :

$$\partial_{\mathbf{n}_+} (u - u^{\text{inc}}) = T_+ (u - u^{\text{inc}}).$$

Equivalently it can be written as

$$\partial_{\mathbf{n}_+} u = T_+ u + \rho \quad \text{on } \Gamma_+, \quad (3.5)$$

where

$$\rho = \partial_{\mathbf{n}_+} u^{\text{inc}} - T_+ u^{\text{inc}}. \quad (3.6)$$

Similarly, for any given u on Γ_- , define the boundary operator T_- :

$$T_- u = \int_{\mathbb{R}} i\beta_- \hat{u}(\xi, y_-) e^{i\xi x} d\xi,$$

where

$$\beta_-^2(\xi) = \kappa_-^2 - |\xi|^2 \quad \text{with } \text{Im}\beta_-(\xi) > 0.$$

Thus, we deduce a transparent boundary condition on Γ_- :

$$\partial_{\mathbf{n}_-} u = T_- u, \quad (3.7)$$

where \mathbf{n}_- is the unit outward normal on Γ_- , i.e., $\mathbf{n}_- = (0, -1)^\top$.

To summarize, the problem (2.5) with the point incident field given in (2.2) and the radiation condition is reduced to the following problem:

$$\begin{aligned} \Delta u + \kappa^2 u &= 0 \quad \text{in } \Omega, \\ \partial_{\mathbf{n}_+} u &= T_+ u + \rho \quad \text{on } \Gamma_+, \\ \partial_{\mathbf{n}_-} u &= T_- u \quad \text{on } \Gamma_-, \end{aligned} \quad (3.8)$$

with κ and ρ given by (2.4) and (3.6), respectively.

Remark 3.1. *Clearly, the transparent boundary conditions (3.5) and (3.7) are nonlocal in the physical domain. However, they are local boundary conditions in the frequency domain. In fact, taking the Fourier transform of (3.5) and (3.7) on both sides, we have*

$$\partial_{\mathbf{n}_\pm} \hat{u}(\xi, y_\pm) = \widehat{T_\pm u} = i\beta_\pm(\xi) \hat{u}(\xi, y_\pm). \quad (3.9)$$

This observation is critical and makes it possible to derive an analytical solution in Section 4.

In order to derive some estimates on the boundary operators, it is useful to introduce the following notations. Define

$$\kappa_\pm^2 = \varphi_\pm + i\psi_\pm,$$

where

$$\varphi_\pm = \text{Re}\kappa_\pm^2 \quad \text{and} \quad \psi_\pm = \text{Im}\kappa_\pm^2.$$

Denote by

$$\beta_\pm^2 = \kappa_\pm^2 - |\xi|^2 = \phi_\pm + i\psi_\pm, \quad (3.10)$$

where

$$\phi_\pm = \text{Re}\kappa_\pm^2 - |\xi|^2 = \varphi_\pm - |\xi|^2. \quad (3.11)$$

A simple calculations gives

$$\beta_\pm = a_\pm + ib_\pm,$$

where

$$a_\pm = \text{Re}\beta_\pm = \left(\frac{\sqrt{\phi_\pm^2 + \psi_\pm^2} + |\phi_\pm|}{2} \right)^{1/2} \quad \text{and} \quad b_\pm = \text{Im}\beta_\pm = \left(\frac{\sqrt{\phi_\pm^2 + \psi_\pm^2} - |\phi_\pm|}{2} \right)^{1/2}. \quad (3.12)$$

It follows from (3.11) that

$$\varphi_\pm \geq \phi_\pm > -\infty \quad \text{and} \quad |\phi_\pm| \geq 0,$$

which yields

$$a_\pm \geq \left(\frac{\text{Im}\kappa_\pm^2}{2} \right)^{1/2} \quad \text{and} \quad \left(\frac{\text{Im}\kappa_\pm^2}{2} \right)^{1/2} \geq b_\pm > 0. \quad (3.13)$$

Lemma 3.1. *The boundary operator $T_\pm : H^{1/2}(\Gamma_\pm) \rightarrow H^{-1/2}(\Gamma_\pm)$ is continuous.*

Proof. For any $u, v \in H^{1/2}(\Gamma_{\pm})$, it follows from the definitions (2.7), (3.5), and (3.7) that

$$\langle T_{\pm}u, v \rangle = i \int_{\mathbb{R}} \beta_{\pm} \hat{u} \bar{v} d\xi = i \int_{\mathbb{R}} \beta_{\pm} (1 + |\xi|^2)^{-1/2} \times (1 + |\xi|^2)^{1/4} \hat{u} \times (1 + |\xi|^2)^{1/4} \bar{v} d\xi.$$

To prove the lemma, it is required to estimate

$$\frac{|\beta_{\pm}|}{(1 + |\xi|^2)^{1/2}} = \left[\frac{\psi_{\pm}^2 + \phi_{\pm}^2}{(1 + \varphi_{\pm} - \phi_{\pm})^2} \right]^{1/4}.$$

Let

$$F_{\pm}(t) = \frac{\psi_{\pm}^2 + t^2}{(1 + \varphi_{\pm} - t)^2}, \quad -\infty < t \leq \varphi_{\pm}.$$

It can be verified that $F_{\pm}(t)$ decreases for $-\infty < t \leq K_{\pm} = -\psi_{\pm}^2/(1 + \varphi_{\pm})$ and increases for $K_{\pm} \leq t \leq \varphi_{\pm}$. Hence, a simple calculation yields

$$F_{\pm}(t) \leq \max\{F_{\pm}(-\infty), F_{\pm}(\varphi_{\pm})\} = \max\{1, |\kappa_{\pm}|^4\}.$$

Combining above estimates yields

$$|\langle T_{\pm}u, v \rangle| \leq \gamma_{\pm} \|u\|_{H^{1/2}(\Gamma_{\pm})} \|v\|_{H^{1/2}(\Gamma_{\pm})},$$

where

$$\gamma_{\pm} = \max\{1, |\kappa_{\pm}|\}.$$

Thus, from Lemma 2.2, we have

$$\|T_{\pm}u\|_{H^{-1/2}(\Gamma_{\pm})} \leq \sup_{v \in H^{1/2}(\Gamma_{\pm})} \frac{|\langle T_{\pm}u, v \rangle|}{\|v\|_{H^{1/2}(\Gamma_{\pm})}} \leq \gamma_{\pm} \|u\|_{H^{1/2}(\Gamma_{\pm})}.$$

□

Lemma 3.2. *Let $u \in H^{1/2}(\Gamma_{\pm})$. It holds that $\operatorname{Re}\langle T_{\pm}u, u \rangle \leq 0$ and $\operatorname{Im}\langle T_{\pm}u, u \rangle \geq 0$. If $\operatorname{Re}\langle T_{\pm}u, u \rangle = 0$ or $\operatorname{Im}\langle T_{\pm}u, u \rangle = 0$, then $u = 0$.*

Proof. By definitions (2.7), (3.5), (3.7), and (3.12), we find

$$\langle T_{\pm}u, u \rangle = i \int_{\mathbb{R}} \beta_{\pm} |\hat{u}|^2 d\xi = i \int_{\mathbb{R}} a_{\pm} |\hat{u}|^2 d\xi - \int_{\mathbb{R}} b_{\pm} |\hat{u}|^2 d\xi.$$

Taking the real part gives

$$\operatorname{Re}\langle T_{\pm}u, u \rangle = - \int_{\mathbb{R}} b_{\pm} |\hat{u}|^2 d\xi \leq 0,$$

and taking the imaginary part yields

$$\operatorname{Im}\langle T_{\pm}u, u \rangle = \int_{\mathbb{R}} a_{\pm} |\hat{u}|^2 d\xi \geq 0.$$

Furthermore, $\operatorname{Re}\langle T_{\pm}u, u \rangle = 0$ implies $\hat{u} = 0$ and $\operatorname{Im}\langle T_{\pm}u, u \rangle = 0$ implies $\hat{u} = 0$. Hence, either $\operatorname{Re}\langle T_{\pm}u, u \rangle = 0$ implies $u = 0$ or $\operatorname{Im}\langle T_{\pm}u, u \rangle = 0$ implies $u = 0$. □

3.2 Well-posedness

We now present a variational formulation of the Helmholtz equation (3.8) in $H^1(\Omega)$ and give a simple proof of the well-posedness for the boundary value problem.

Multiplying (3.8) by the complex conjugate of a test function $v \in H^1(\Omega)$, integrating over Ω , and using integration by parts (recall that Lemma 2.2 implies the lateral boundary integrals vanish as $|x| \rightarrow \infty$), we deduce the variational formulation for the scattering problem (3.8): find $u \in H^1(\Omega)$ such that

$$a(u, v) = \langle \rho, v \rangle_{\Gamma_+} \quad \text{for all } v \in H^1(\Omega), \quad (3.14)$$

with the sesquilinear form

$$a(u, v) = \int_{\Omega} (\nabla u \cdot \nabla \bar{v} - \kappa^2 u \bar{v}) - \int_{\Gamma_+} T_+ u \bar{v} - \int_{\Gamma_-} T_- u \bar{v}, \quad (3.15)$$

and the linear functional

$$\langle \rho, v \rangle_{\Gamma_+} = \int_{\Gamma_+} \rho \bar{v}. \quad (3.16)$$

Lemma 3.3. *Under the condition (2.1), we have $\rho \in H^s(\Gamma_+)$ for all $s \in \mathbb{R}$.*

Proof. Recall

$$\rho(x, y; x_0, y_0) = \partial_{\mathbf{n}_+} u^{\text{inc}}(x, y; x_0, y_0) - T_+ u^{\text{inc}}(x, y; x_0, y_0). \quad (3.17)$$

It suffices to prove

$$\| \rho(x, y_+; x_0, y_0) \|_{H^s(\Gamma_+)}^2 = \int_{\mathbb{R}} (1 + |\xi|^2)^s |\hat{\rho}(\xi, y_+; x_0, y_0)|^2 d\xi < \infty.$$

Let

$$\hat{\rho}^{\text{inc}}(\xi, y; x_0, y_0) = \int_{\mathbb{R}} u^{\text{inc}}(x, y; x_0, y_0) e^{-i\xi x} dx$$

be the Fourier transform of $u^{\text{inc}}(x, y; x_0, y_0)$ with respect to x . Since the incident field is taken as the fundamental solution for the Helmholtz equation with number κ_+ , it can be explicitly written as

$$\hat{\rho}^{\text{inc}}(\xi, y; x_0, y_0) = \frac{i}{2\beta_+(\xi)} e^{i\beta_+|y-y_0|} e^{-i\xi x_0}.$$

Noticing $y_0 > y_+$, we have by simple calculations that

$$\partial_{\mathbf{n}_+} \hat{u}^{\text{inc}}(x, y; x_0, y_0)|_{y=y_+} = -\frac{1}{2} e^{i\beta_+(y_0-y_+)} e^{-i\xi x_0}. \quad (3.18)$$

Using the definition of the boundary operator T_+ , we have

$$T_+ u^{\text{inc}}(x, y_+; x_0, y_0) = \int_{\mathbb{R}} i\beta_+(\xi) \hat{u}^{\text{inc}}(\xi, y_+; x_0, y_0) e^{i\xi x} d\xi,$$

which gives after taking the Fourier transform

$$\widehat{T_+ u^{\text{inc}}}(\xi, y_+; x_0, y_0) = i\beta_+(\xi) \hat{u}^{\text{inc}}(\xi, y_+; x_0, y_0) = -\frac{1}{2} e^{i\beta_+(y_0-y_+)} e^{-i\xi x_0}. \quad (3.19)$$

Combining (3.17), (3.18), and (3.19), we obtain after plugging (3.12) that

$$\hat{\rho}(\xi, y_+; x_0, y_0) = -e^{i\beta_+(y_0-y_+)} e^{-i\xi x_0} = -e^{i\alpha_+(\xi)(y_0-y_+)} e^{-b_+(\xi)(y_0-y_+)} e^{-i\xi x_0},$$

which gives

$$|\hat{\rho}(\xi, y_+; x_0, y_0)|^2 = e^{-2b_+(\xi)(y_0 - y_+)}.$$

Using (3.11) and (3.12) yields

$$b_+(\xi) = \left(\frac{\sqrt{(|\xi|^2 - \varphi_+)^2 + \psi_+^2} + |\xi|^2 - \varphi_+}{2} \right)^{1/2},$$

where $\varphi_+ = \operatorname{Re}\kappa_+^2$ and $\psi_+ = \operatorname{Im}\kappa_+^2$ are fixed constants. It is easy to check that $b_+(\xi) \sim |\xi|$ as $|\xi| \rightarrow \infty$. Hence we deduce that

$$\begin{aligned} \|\rho(x, y_+; x_0, y_0)\|_{H^s(\Gamma_+)}^2 &= \int_{\mathbb{R}} (1 + |\xi|^2)^s |\hat{\rho}(\xi, y_+; x_0, y_0)|^2 d\xi \\ &= \int_{\mathbb{R}} (1 + |\xi|^2)^s e^{-2b_+(\xi)(y_0 - y_+)} d\xi < \infty \end{aligned}$$

for all $s \in \mathbb{R}$, which completes the proof. \square

Remark 3.2. *If the incident field is a plane wave $u^{\text{inc}}(x, y) = e^{i\alpha x - i\beta y}$, where $\alpha = \kappa_+ \sin \theta$, $\beta = \kappa_+ \cos \theta$, and θ is the angel of incidence, then the linear functional (3.16) is not well-defined. In fact, a simple calculation yields*

$$\rho(x) = -2i\beta e^{i\alpha x - i\beta y_+} = -2i\beta e^{-i\beta y_+} e^{i\operatorname{Re}\kappa_+ \sin \theta x} e^{-i\operatorname{Im}\kappa_+ \sin \theta x}.$$

Thus, it can be easily verified that $\|\rho\|_{L^2(\Gamma_+)} = \infty$, i.e., $\rho \notin L^2(\Gamma_+)$. This is the reason why we consider the incident field generated from a point source instead of the plane wave.

Theorem 3.1. *Under the condition (2.1), the variational problem (3.14) has a unique solution in $H^1(\Omega)$ satisfying*

$$\|u\|_{H^1(\Omega)} \leq \left(1 + \frac{1 + \alpha}{\beta}\right) \|\partial_{\mathbf{n}_+} u^{\text{inc}} - T_+ u^{\text{inc}}\|_{H^{-1/2}(\Gamma_+)}. \quad (3.20)$$

Proof. It suffices to prove the continuity and coercivity of the sesquilinear form a . The continuity follows directly from the Cauchy–Schwarz inequality, Lemma 3.1, and Lemma 2.3:

$$\begin{aligned} |a(u, v)| &\leq C_1 \|u\|_{H^1(\Omega)} \|v\|_{H^1(\Omega)} + C_2 \|T_+ u\|_{H^{-1/2}(\Gamma_+)} \|v\|_{H^{1/2}(\Gamma_+)} \\ &\quad + C_3 \|T_- u\|_{H^{-1/2}(\Gamma_-)} \|v\|_{H^{1/2}(\Gamma_-)} \\ &\leq C_1 \|u\|_{H^1(\Omega)} \|v\|_{H^1(\Omega)} + C_2 \|u\|_{H^{1/2}(\Gamma_+)} \|v\|_{H^{1/2}(\Gamma_+)} \\ &\quad + C_3 \|u\|_{H^{1/2}(\Gamma_-)} \|v\|_{H^{1/2}(\Gamma_-)} \\ &\leq C \|u\|_{H^1(\Omega)} \|v\|_{H^1(\Omega)}. \end{aligned}$$

Taking the real part of the sesquilinear form a and using Lemma 3.2 yield

$$\begin{aligned} \operatorname{Re}[a(u, u)] &= \int_{\Omega} |\nabla u|^2 - \int_{\Omega} \operatorname{Re}(\kappa^2) |u|^2 - \operatorname{Re}\langle T_+ u, u \rangle_{\Gamma_+} - \operatorname{Re}\langle T_- u, u \rangle_{\Gamma_-} \\ &\geq \int_{\Omega} |\nabla u|^2 - \int_{\Omega} \operatorname{Re}(\kappa^2) |u|^2 \geq \|\nabla u\|_{L^2(\Omega)}^2 - \alpha \|u\|_{L^2(\Omega)}^2. \end{aligned}$$

Taking the imaginary part of the sesquilinear form a and using Lemma 3.2 give

$$\operatorname{Im}[a(u, u)] = - \int_{\Omega} \operatorname{Im}(\kappa^2) |u|^2 - \operatorname{Im}\langle T_+ u, u \rangle_{\Gamma_+} - \operatorname{Im}\langle T_- u, u \rangle_{\Gamma_-} \leq - \int_{\Omega} \operatorname{Im}(\kappa^2) |u|^2,$$

which, along with (2.1), leads to

$$|\operatorname{Im}[a(u, u)]| \geq \beta \|u\|_{L^2(\Omega)}^2.$$

Denote $\gamma = (1 + \alpha)/\beta > 0$. It follows from

$$|a(u, u)| \geq |\operatorname{Re}[a(u, u)]| \quad \text{and} \quad \gamma|a(u, u)| \geq \gamma|\operatorname{Im}[a(u, u)]|$$

that we have

$$\begin{aligned} (1 + \gamma)|a(u, u)| &\geq |\operatorname{Re}[a(u, u)]| + \gamma|\operatorname{Im}[a(u, u)]| \\ &\geq \|\nabla u\|_{L^2(\Omega)}^2 - \alpha \|u\|_{L^2(\Omega)}^2 + \gamma\beta \|u\|_{L^2(\Omega)}^2 \geq \|u\|_{H^1(\Omega)}^2. \end{aligned}$$

It follows from the Lax–Milgram lemma and Lemma 3.3 that there exists a unique weak solution of the variational problem (3.14) in $H^1(\Omega)$ satisfying (3.20). \square

Remark 3.3. *Classical results from the theory of elliptic partial differential equations in Gilbarg and Trudinger [28] indicate that if $\rho = \partial_{\mathbf{n}_+} u^{\text{inc}} - T_+ u^{\text{inc}} \in H^{1/2}(\Gamma_+)$, then the unique solution satisfies*

$$\|u\|_{H^2(\Omega)} \leq C \|\partial_{\mathbf{n}_+} u^{\text{inc}} - T_+ u^{\text{inc}}\|_{H^{1/2}(\Gamma_+)}, \quad (3.21)$$

where C is a positive constant.

4 Boundary perturbation method

In this section, we study the method of boundary perturbation and deduce an analytical solution for the unbounded rough surface scattering problem. Here the scattering profile f is assumed to be a bounded and twice continuously differentiable function. First, the scattering problem is formulated as a transmission problem where the scattering profile plays the role of the interface. Then the transformed field expansion method (cf. [36]) is applied to derive the analytical solution as an infinite series.

4.1 Transmission problem

We formulate the variational problem (3.14) into an equivalent transmission problem or interface problem, which is of more convenient form for the method of boundary perturbation.

Denote $\Omega_+ = \Omega_f^+ \cap \Omega$ and $\Omega_- = \Omega_f^- \cap \Omega$, as seen in Figure 1. Consider the Helmholtz equation (2.3) in Ω_+ and Ω_- , respectively:

$$\Delta u^+ + \kappa_+^2 u^+ = 0 \quad \text{in } \Omega_+, \quad (4.1)$$

$$\Delta u^- + \kappa_-^2 u^- = 0 \quad \text{in } \Omega_-. \quad (4.2)$$

Recall the nonlocal transparent boundary conditions (3.5) and (3.7):

$$\partial_{\mathbf{n}_+} u^+ = T_+ u^+ + \rho \quad \text{on } \Gamma_+, \quad (4.3)$$

$$\partial_{\mathbf{n}_-} u^- = T_- u^- \quad \text{on } \Gamma_-. \quad (4.4)$$

Following from the jump conditions, we obtain that the field and its normal derivative are continuous across the scattering surface S , i.e.,

$$u^+(x, f(x)) = u^-(x, f(x)), \quad (4.5)$$

$$\partial_{\mathbf{n}} u^+(x, f(x)) = \partial_{\mathbf{n}} u^-(x, f(x)), \quad (4.6)$$

where $\mathbf{n} = (n_1, n_2)^\top$ is the unit normal vector pointing from Ω_+ to Ω_- . Explicitly, we have

$$n_1 = \frac{f'(x)}{\sqrt{1 + [f'(x)]^2}} \quad \text{and} \quad n_2 = -\frac{1}{\sqrt{1 + [f'(x)]^2}}.$$

Hence, the transmission problem is to find the fields u^+ and u^- , which satisfy the Helmholtz equations (4.1) and (4.2), the continuity conditions (4.5) and (4.6), and the boundary conditions (4.3) and (4.4).

Remark 4.1. *It is easy to see that the solution u of the variational problem (3.14) restricted to Ω_+ and Ω_- , i.e., $u^+ = u|_{\Omega_+}$ and $u^- = u|_{\Omega_-}$, is the solution of the transmission problem (4.1)–(4.6). Conversely, the solution u^+ and u^- of the transmission problem (4.1)–(4.6) constructs the solution of the variational problem (3.14) in the domain Ω .*

4.2 Transformed field expansion

The transformed field expansion method, as applied to the unbounded rough surface scattering, begins with the change of variables:

$$x_1 = x, \quad y_1 = y_+ \left(\frac{y - f}{y_+ - f} \right), \quad f < y < y_+,$$

and

$$x_2 = x, \quad y_2 = y_- \left(\frac{y - f}{y_- - f} \right), \quad y_- < y < f,$$

which maps the perturbed domains Ω_+ and Ω_- to unperturbed strip domains D_+ and D_- , respectively. We now seek to restate the transmission problem (4.1)–(4.6) in these transformed coordinates. It is easy to verify the differentiation rules

$$\begin{aligned} \partial_x &= \partial_{x_1} - f' \left(\frac{y_+ - y_1}{y_+ - f} \right) \partial_{y_1}, \\ \partial_y &= \left(\frac{y_+}{y_+ - f} \right) \partial_{y_1}, \end{aligned}$$

for $f < y < y_+$, and

$$\begin{aligned} \partial_x &= \partial_{x_2} - f' \left(\frac{y_- - y_2}{y_- - f} \right) \partial_{y_2}, \\ \partial_y &= \left(\frac{y_-}{y_- - f} \right) \partial_{y_2}, \end{aligned}$$

for $y_- < y < f$.

Introduce new functions $w^+(x_1, y_1) = u^+(x, y)$ and $w^-(x_2, y_2) = u^-(x, y)$ under the transformation. It can be verified after tedious but straightforward calculations that w^+ and w^- , upon dropping the subscript, satisfy the equation

$$c_1^+ \frac{\partial^2 w^+}{\partial x^2} + c_2^+ \frac{\partial^2 w^+}{\partial y^2} + c_3^+ \frac{\partial^2 w^+}{\partial x \partial y} + c_4^+ \frac{\partial w^+}{\partial y} + c_1^+ \kappa_+^2 w^+ = 0, \quad 0 < y < y_+, \quad (4.7)$$

$$c_1^- \frac{\partial^2 w^-}{\partial x^2} + c_2^- \frac{\partial^2 w^-}{\partial y^2} + c_3^- \frac{\partial^2 w^-}{\partial x \partial y} + c_4^- \frac{\partial w^-}{\partial y} + c_1^- \kappa_-^2 w^- = 0, \quad y_- < y < 0, \quad (4.8)$$

where

$$\begin{aligned} c_1^\pm &= (y_\pm - f)^2, \\ c_2^\pm &= [f'(y_\pm - y)]^2 + y_\pm^2, \\ c_3^\pm &= -2f'(y_\pm - y)(y_\pm - f), \\ c_4^\pm &= -(y_\pm - y)[f''(y_\pm - f) + 2(f')^2]. \end{aligned}$$

The nonlocal transparent boundary conditions are

$$\partial_{\mathbf{n}_+} w^+ = \partial_y w^+ = \left(1 - \frac{f}{y_+}\right) (T_+ w^+ + \rho), \quad y = y_+, \quad (4.9)$$

$$\partial_{\mathbf{n}_-} w^- = -\partial_y w^- = \left(1 - \frac{f}{y_-}\right) T_- w^-, \quad y = y_-. \quad (4.10)$$

The continuity conditions at the interface $y = 0$ reduce to

$$w^+(x, 0) = w^-(x, 0), \quad (4.11)$$

$$\left(\frac{y_+}{y_+ - f}\right) \partial_y w^+(x, 0) = \left(\frac{y_-}{y_- - f}\right) \partial_y w^-(x, 0). \quad (4.12)$$

Now, we use a classical boundary perturbation argument. Let $f = \varepsilon g$ with ε sufficiently small, and consider the formal expansions of (w^+, w^-) in a power series of ε :

$$w^+(x, y; \varepsilon) = \sum_{n=0}^{\infty} w_n^+(x, y) \varepsilon^n \quad \text{and} \quad w^-(x, y; \varepsilon) = \sum_{n=0}^{\infty} w_n^-(x, y) \varepsilon^n. \quad (4.13)$$

Substituting $f = \varepsilon g$ into c_j^\pm and inserting the above expansions into (4.7) and (4.8), we may derive the recursions for w_n^+ and w_n^- :

$$\frac{\partial^2 w_n^+}{\partial x^2} + \frac{\partial^2 w_n^+}{\partial y^2} + \kappa_+^2 w_n^+ = v_n^+, \quad 0 < y < y_+, \quad (4.14)$$

$$\frac{\partial^2 w_n^-}{\partial x^2} + \frac{\partial^2 w_n^-}{\partial y^2} + \kappa_-^2 w_n^- = v_n^-, \quad y_- < y < 0, \quad (4.15)$$

where

$$\begin{aligned} v_n^\pm &= \frac{2g}{y_\pm} \frac{\partial^2 w_{n-1}^\pm}{\partial x^2} + \frac{2g'(y_\pm - y)}{y_\pm} \frac{\partial^2 w_{n-1}^\pm}{\partial x \partial y} + \frac{g''(y_\pm - y)}{y_\pm} \frac{\partial w_{n-1}^\pm}{\partial y} + \frac{2\kappa_\pm^2 g}{y_\pm} w_{n-1}^\pm \\ &\quad - \frac{g^2}{y_\pm^2} \frac{\partial^2 w_{n-2}^\pm}{\partial x^2} - \frac{(g')^2 (y_\pm - y)^2}{y_\pm^2} \frac{\partial^2 w_{n-2}^\pm}{\partial y^2} - \frac{2gg'(y_\pm - y)}{y_\pm^2} \frac{\partial^2 w_{n-2}^\pm}{\partial x \partial y} \\ &\quad + \frac{[2(g')^2 - gg''](y_\pm - y)}{y_\pm^2} \frac{\partial w_{n-2}^\pm}{\partial y} - \frac{\kappa_\pm^2 g^2}{y_\pm^2} w_{n-2}^\pm. \end{aligned}$$

The nonlocal boundary conditions (4.9) and (4.10) become

$$\partial_y w_n^+ - T_+ w_n^+ = \rho_n^+, \quad y = y_+, \quad (4.16)$$

$$\partial_y w_n^- + T_- w_n^- = \rho_n^-, \quad y = y_-, \quad (4.17)$$

where

$$\begin{aligned} \rho_0^+ &= \rho, & \rho_1^+ &= -\left(\frac{g}{y_+}\right) T_+ w_0^+ - \left(\frac{g}{y_+}\right) \rho, & \rho_n^+ &= -\left(\frac{g}{y_+}\right) T_+ w_{n-1}^+, & n &= 2, 3, \dots, \\ \rho_0^- &= 0, & \rho_n^- &= \left(\frac{g}{y_-}\right) T_- w_{n-1}^-, & n &= 1, 2, \dots \end{aligned}$$

The continuity conditions at the interface $y = 0$ reduce to

$$w_n^+(x, 0) - w_n^-(x, 0) = 0, \quad (4.18)$$

$$\partial_y w_n^+(x, 0) - \partial_y w_n^-(x, 0) = \varrho_n, \quad (4.19)$$

where

$$\varrho_0 = 0, \quad \varrho_n = \left(\frac{g}{y_-}\right) \partial_y w_{n-1}^+ - \left(\frac{g}{y_+}\right) \partial_y w_{n-1}^-, \quad n = 1, 2, \dots$$

Note that the Helmholtz problem (4.14)–(4.15) for the current terms w_n^\pm involve some non-homogeneous terms v_n^\pm , ρ_n^\pm , and ϱ_n , which only depend on previous two terms w_{n-1}^\pm and w_{n-2}^\pm . Thus, the transmission problems (4.14)–(4.19) indeed can be solved in a recursive manner starting from $n = 0$.

Taking the Fourier transform of (4.14) and (4.15) with respect to the variable x yields

$$\frac{\partial^2 \hat{w}_n^+}{\partial y^2} + (\kappa_+^2 - \xi^2) \hat{w}_n^+ = \hat{v}_n^+, \quad 0 < y < y_+, \quad (4.20)$$

$$\frac{\partial^2 \hat{w}_n^-}{\partial y^2} + (\kappa_-^2 - \xi^2) \hat{w}_n^- = \hat{v}_n^-, \quad y_- < y < 0. \quad (4.21)$$

According to Remark 3.1, the nonlocal boundary conditions become local boundary condition in the frequency domain:

$$\partial_y \hat{w}_n^+ - i\beta_+ \hat{w}_n^+ = \hat{\rho}_n^+, \quad y = y_+, \quad (4.22)$$

$$\partial_y \hat{w}_n^- + i\beta_- \hat{w}_n^- = \hat{\rho}_n^-, \quad y = y_-. \quad (4.23)$$

The continuity conditions reduce to

$$\hat{w}_n^+(\xi, 0) - \hat{w}_n^-(\xi, 0) = 0, \quad (4.24)$$

$$\partial_y \hat{w}_n^+(\xi, 0) - \partial_y \hat{w}_n^-(\xi, 0) = \hat{\varrho}_n. \quad (4.25)$$

After taking the Fourier transform, the two-dimensional problem (4.14)–(4.19) reduces to the one-dimensional transmission problem (4.20)–(4.25) in the frequency domain. This problem falls in the class of so-called two-point boundary value problem, whose detailed solution is discussed in Appendix B. An application of Theorem B.1, along with (B.13) and (B.23), leads to the following explicit solution of the transmission problem.

Theorem 4.1. *Let f be in $C^2(\mathbb{R})$ and assume that (w^+, w^-) admit the asymptotic expansions (4.13). Then the fields (w_n^+, w_n^-) are determined as the unique solution of the transmission problem (4.20)–(4.25), given explicitly as*

$$\hat{w}_n^+(\xi, y) = e^{i\beta_+ y} \hat{w}_n^+(\xi, 0) - K_1^+(\xi, y) \hat{\rho}_n^+ + \int_0^{y_+} K_2^+(\xi, y, z) \hat{v}_n^+(z) dz, \quad (4.26)$$

$$\hat{w}_n^-(\xi, y) = e^{-i\beta_- y} \hat{w}_n^-(\xi, 0) + K_1^-(\xi, y) \hat{\rho}_n^- - \int_{y_-}^0 K_2^-(\xi, y, z) \hat{v}_n^-(z) dz, \quad (4.27)$$

where

$$K_1^+(\xi, y) = \frac{e^{i\beta_+ y} (e^{-i\beta_+ y} - e^{i\beta_+ y})}{2i\beta_+},$$

$$K_1^-(\xi, y) = \frac{e^{-i\beta_- y} (e^{i\beta_- y} - e^{-i\beta_- y})}{2i\beta_-},$$

and

$$K_2^+(\xi, y, z) = \begin{cases} \frac{e^{i\beta_+ y} (e^{-i\beta_+ z} - e^{i\beta_+ z})}{2i\beta_+} & \text{if } z < y, \\ \frac{e^{i\beta_+ z} (e^{-i\beta_+ y} - e^{i\beta_+ y})}{2i\beta_+} & \text{if } z > y, \end{cases}$$

$$K_2^-(\xi, y, z) = \begin{cases} \frac{e^{-i\beta_- z} (e^{-i\beta_- y} - e^{i\beta_- y})}{2i\beta_-} & \text{if } z < y, \\ \frac{e^{-i\beta_- y} (e^{-i\beta_- z} - e^{i\beta_- z})}{2i\beta_-} & \text{if } z > y, \end{cases}$$

with

$$\hat{w}_n^+(\xi, 0) = \hat{w}_n^-(\xi, 0) = \frac{-i}{\beta_+ + \beta_-} \times \left[\hat{\varrho}_n + e^{-i\beta_- y} \hat{\rho}_n^- - e^{i\beta_+ y} \hat{\rho}_n^+ + \int_0^{y_+} e^{i\beta_+ z} \hat{v}_n^+(z) dz + \int_{y_-}^0 e^{-i\beta_- z} \hat{v}_n^-(z) dz \right]. \quad (4.28)$$

Remark 4.2. Under the assumption that f has two continuous derivative, i.e., $f \in C^2(\mathbb{R})$, we may follow the same techniques by Nicholls and Reitich [35] to show inductively, for ε sufficiently small, that

$$\|w_n^+\|_{H^2(\Omega)} \leq K_+ \quad \text{and} \quad \|w_n^-\|_{H^2(\Omega)} \leq K_-, \quad \forall n \geq 0,$$

where K_+ and K_- are two positive constants independent of the index n . Therefore, the power series for w^+ and w^- in (4.13) converge for sufficiently small ε .

5 Concluding remarks

We proposed in this paper a variational formulation for the scattering problem by an unbounded penetrable rough surface, and derived the analytical solution when the scattering surface is assumed to be a sufficiently small and smooth perturbation of a plane surface.

In the first part, we reduced the scattering problem to a boundary value problem using transparent boundary condition, and proved the uniqueness and existence of the weak solution for the variational problem. In the second part, by using the transformed field expansion and Fourier transform, we converted the original two-dimensional problem with complex scattering surface into a sequence of one-dimensional two-point boundary value problems with decoupled boundary conditions in the frequency space for which the analytical solution can be explicitly expressed by using the integrated solution method.

While the analytical solution given in Theorem 4.1 is of interest for many purposes, it is not very convenient to use in practice due to the lack of discrete Fourier transform on the infinite domain \mathbb{R} . In [29], we shall extend the numerical method in [27, 37] to construct a practical algorithm for solving this problem.

An essential assumption we made is that $\text{Im}\kappa_{\pm}^2 \neq 0$. A challenging problem is to study the infinite rough surface scattering problem in lossless medium, i.e., $\text{Im}\kappa_{\pm}^2 = 0$. Without energy decay, the capacity operator introduced in this paper is unbounded and the proposed method can not be directly applied to this case. We hope to be able to address these issues by studying the limiting absorption principle in the future. We also intend to extend the method to more complicated three-dimensional Maxwell's equations.

A A two-point boundary value problem

In this section, the integrated solution method is briefly introduced to solve a two-point boundary value problem. We refer to Zhang [47] for the details of the integrated solutions of ordinary differential equation system and two-point boundary value problems.

Consider the two-point boundary value problem

$$\mathbf{u}'(y) + M(y)\mathbf{u}(y) = \mathbf{f}(y), \quad (\text{A.1})$$

$$A_0\mathbf{u}(y)|_{y=0} = \mathbf{r}_0, \quad (\text{A.2})$$

$$B_1\mathbf{u}(y)|_{y=L} = \mathbf{s}_1, \quad (\text{A.3})$$

where $\mathbf{f}(y) \in \mathbb{C}^m$ are m -dimensional vector fields, $\mathbf{r}_0 \in \mathbb{C}^{m_1}$ and $\mathbf{s}_1 \in \mathbb{C}^{m_2}$ are given m_1 - and m_2 -dimensional vector fields, respectively, $M(y) \in \mathbb{C}^{m \times m}$ is an $m \times m$ matrix, and $A_0 \in \mathbb{C}^{m_1 \times m}$ and $B_1 \in \mathbb{C}^{m_2 \times m}$ are full rank matrices with $m_1 + m_2 = m$, i.e., $\text{rank}A_0 = m_1$ and $\text{rank}B_1 = m_2$.

Let $\Phi(y)$ be the fundamental matrix of the system

$$\Phi'(y) + M(y)\Phi(y) = \mathbf{0}, \quad (\text{A.4})$$

$$\Phi(0) = I, \quad (\text{A.5})$$

where I is the $m \times m$ identity matrix.

Theorem A.1. *The two-point boundary value problem (A.1)–(A.3) has a unique solution if and only if*

$$\det \begin{bmatrix} A_0 \\ B_1\Phi(L) \end{bmatrix} \neq 0. \quad (\text{A.6})$$

Let the pair of functions $\{A(y), \mathbf{r}(y)\}$ and $\{B(y), \mathbf{s}(y)\}$ be the integrated solutions of the problems (A.1)–(A.2) and (A.1)–(A.3), respectively, then there exist $D_0(A, y) \in \mathbb{C}^{m_1 \times m_1}$ and $D_1(B, y) \in \mathbb{C}^{m_2 \times m_2}$ such that

$$A' = AM + D_0A, \quad A(0) = A_0, \quad (\text{A.7})$$

$$\mathbf{r}' = A\mathbf{f} + D_0\mathbf{r}, \quad \mathbf{r}(0) = \mathbf{r}_0, \quad (\text{A.8})$$

and

$$B' = BM + D_1B, \quad B(L) = B_1, \quad (\text{A.9})$$

$$\mathbf{s}' = B\mathbf{f} + D_1\mathbf{s}, \quad \mathbf{s}(L) = \mathbf{s}_1. \quad (\text{A.10})$$

Theorem A.2. *If the two-point boundary value problem (A.1)–(A.3) has a unique solution, then the matrix*

$$\begin{bmatrix} A(y) \\ B(y) \end{bmatrix} \in \mathbb{C}^{m \times m}$$

is nonsingular.

Theorem A.3. *The two-point boundary value problem (A.1)–(A.3) is equivalent to the linear system*

$$\begin{bmatrix} A(y) \\ B(y) \end{bmatrix} \mathbf{u}(y) = \begin{bmatrix} \mathbf{r}(y) \\ \mathbf{s}(y) \end{bmatrix}. \quad (\text{A.11})$$

B A transmission problem

In this section, we discuss the solution of a transmission problem in details. Consider the second order boundary value problem

$$u_+'' + \lambda_+^2 u_+ = f_+, \quad 0 < y < y_+, \quad (\text{B.1})$$

$$u_-'' + \lambda_-^2 u_- = f_-, \quad y_- < y < 0, \quad (\text{B.2})$$

with the boundary conditions

$$\partial_y u_+ - i\lambda_+ u_+ = g_+ \quad \text{at } y = y_+, \quad (\text{B.3})$$

$$\partial_y u_- + i\lambda_- u_- = g_- \quad \text{at } y = y_-, \quad (\text{B.4})$$

and the jump conditions across the interface $y = 0$:

$$u_+(0) - u_-(0) = h_1, \quad (\text{B.5})$$

$$\partial_y u_+(0) - \partial_y u_-(0) = h_2. \quad (\text{B.6})$$

We now convert the second order differential equation into a first order two-point boundary value problem. Let $v_1^+ = u_+$ and $v_2^+ = u_+'$, the second order boundary value problem (B.1) and (B.3) can be formulated into a first order two-point boundary value problem:

$$\mathbf{v}_+' + M_+ \mathbf{v}_+ = \mathbf{f}_+, \quad (\text{B.7})$$

$$A_0^+ \mathbf{v}_+(0) = u_+(0), \quad (\text{B.8})$$

$$B_1^+ \mathbf{v}_+(y_+) = g_+, \quad (\text{B.9})$$

where

$$\mathbf{v}_+ = \begin{bmatrix} v_1^+ \\ v_2^+ \end{bmatrix}, \quad \mathbf{f}_+ = \begin{bmatrix} 0 \\ f_+ \end{bmatrix}, \quad M_+ = \begin{bmatrix} 0 & -1 \\ \lambda_+^2 & 0 \end{bmatrix},$$

and

$$A_0^+ = [1, 0], \quad B_1^+ = [-i\lambda_+, 1].$$

Similarly, let Let $v_1^- = u_-$ and $v_2^- = u_-'$, the second order boundary value problem (B.2) and (B.4) can be formulated into a first order two-point boundary value problem:

$$\mathbf{v}_-' + M_- \mathbf{v}_- = \mathbf{f}_-, \quad (\text{B.10})$$

$$A_0^- \mathbf{v}_-(0) = u_-(0), \quad (\text{B.11})$$

$$B_1^- \mathbf{v}_-(y_-) = g_-, \quad (\text{B.12})$$

where

$$\mathbf{v}_- = \begin{bmatrix} v_1^- \\ v_2^- \end{bmatrix}, \quad \mathbf{f}_- = \begin{bmatrix} 0 \\ f_- \end{bmatrix}, \quad M_- = \begin{bmatrix} 0 & -1 \\ \lambda_-^2 & 0 \end{bmatrix},$$

and

$$A_0^- = [1, 0], \quad B_1^- = [i\lambda_-, 1].$$

Lemma B.1. Given $f_+ \in L^1(0, y_+)$, $u_+(0)$, $g_+ \in \mathbb{R}$. The two-point boundary value problem (B.7)–(B.9) has a unique solution given by

$$u_+(y) = e^{i\lambda_+ y} u_+(0) - K_1^+(y) g_+ + \int_0^{y_+} K_2^+(y, z) f_+(z) dz, \quad (\text{B.13})$$

where

$$K_1^+(y) = \frac{e^{i\lambda_+ y_+} (e^{-i\lambda_+ y} - e^{i\lambda_+ y})}{2i\lambda_+}$$

and

$$K_2^+(y, z) = \begin{cases} \frac{e^{i\lambda_+ y} (e^{-i\lambda_+ z} - e^{i\lambda_+ z})}{2i\lambda_+} & \text{if } z < y, \\ \frac{e^{i\lambda_+ z} (e^{-i\lambda_+ y} - e^{i\lambda_+ y})}{2i\lambda_+} & \text{if } z > y. \end{cases}$$

Proof. Since M_+ is a non-singular matrix, there exists a non-singular matrix Q_+ such that

$$Q_+^{-1} M_+ Q_+ = N_+,$$

where

$$N_+ = \begin{bmatrix} -i\lambda_+ & 0 \\ 0 & i\lambda_+ \end{bmatrix}, \quad Q_+ = \begin{bmatrix} 1 & 1 \\ i\lambda_+ & -i\lambda_+ \end{bmatrix}, \quad \text{and} \quad Q_+^{-1} = \frac{1}{2i\lambda_+} \begin{bmatrix} i\lambda_+ & 1 \\ i\lambda_+ & -1 \end{bmatrix}.$$

A simple calculation yields

$$\det \begin{bmatrix} A_0^+ \\ B_1^+ e^{M_+} \end{bmatrix} = \begin{vmatrix} 1 & 0 \\ i\lambda_+ e^{i\lambda_+} & -e^{-i\lambda_+} \end{vmatrix} = -e^{-i\lambda_+} \neq 0.$$

It follows from Theorem A.1 that the two-point boundary value problem (B.7)–(B.9) has a unique solution.

Let $\{A_+(y), r_+(y)\}$ and $\{B_+(y), s_+(y)\}$ be the integrated solutions of the problems (B.7), (B.8), and (B.7), (B.9), respectively. Taking

$$D_0^+ = i\lambda_+, \quad D_1^+ = -i\lambda_+,$$

we obtain from (A.7)–(A.10) that the integrated solutions satisfy

$$A_+' = A_+ M_+ + i\lambda_+ A_+, \quad A_+(0) = A_0^+, \quad (\text{B.14})$$

$$r_+' = A_+ \mathbf{f}_+ + i\lambda_+ r_+, \quad r_+(0) = u_+(0), \quad (\text{B.15})$$

and

$$B_+' = B_+ M_+ - i\lambda_+ B_+, \quad B_+(y_+) = B_1^+, \quad (\text{B.16})$$

$$s_+' = B_+ \mathbf{f}_+ - i\lambda_+ s_+, \quad s_+(y_+) = g_+. \quad (\text{B.17})$$

Upon solving the above initial value problem, we obtain the integrated solutions

$$A_+ = [A_1^+, A_2^+] = \frac{1}{2i\lambda_+} [i\lambda_+(1 + e^{2i\lambda_+ y}), 1 - e^{2i\lambda_+ y}], \quad (\text{B.18})$$

$$B_+ = [B_1^+, B_2^+] = [-i\lambda_+, 1], \quad (\text{B.19})$$

$$r_+ = e^{i\lambda_+ y} u_+(0) + \int_0^y e^{i\lambda_+(y-z)} A_2^+(z) f_+(z) dz, \quad (\text{B.20})$$

$$s_+ = e^{i\lambda_+(y_+-y)} g_+ - \int_y^{y_+} e^{i\lambda_+(z-y)} f_+(z) dz. \quad (\text{B.21})$$

It follows from Theorem A.3 that the two-point boundary value problem (B.7)–(B.9) is equivalent to the linear system

$$\begin{bmatrix} A_1^+ & A_2^+ \\ B_1^+ & B_2^+ \end{bmatrix} \begin{bmatrix} u_+ \\ u'_+ \end{bmatrix} = \begin{bmatrix} r_+ \\ s_+ \end{bmatrix}.$$

An application of Gram's rule yields

$$u_+ = \frac{r_+ B_2^+ - s_+ A_2^+}{A_1^+ B_2^+ - B_1^+ A_2^+}. \quad (\text{B.22})$$

A simple calculation yields

$$A_1^+ B_2^+ - B_1^+ A_2^+ = 1.$$

Substituting (B.18)–(B.21) into (B.22), we deduce (B.13). \square

Lemma B.2. *Given $f_- \in L^1(y_-, 0)$, $u_-(0)$, $g_- \in \mathbb{R}$. The two-point boundary value problem (B.10)–(B.12) has a unique solution given by*

$$u_-(y) = e^{-i\lambda_- y} u_-(0) + K_1^-(y) g_- - \int_{y_-}^0 K_2^-(y, z) f_-(z) dz, \quad (\text{B.23})$$

where

$$K_1^-(y) = \frac{e^{-i\lambda_- y} (e^{i\lambda_- y} - e^{-i\lambda_- y})}{2i\lambda_-}$$

and

$$K_2^-(y, z) = \begin{cases} \frac{e^{-i\lambda_- z} (e^{-i\lambda_- y} - e^{i\lambda_- y})}{2i\lambda_+} & \text{if } z < y, \\ \frac{e^{-i\lambda_- y} (e^{-i\lambda_- z} - e^{i\lambda_- z})}{2i\lambda_-} & \text{if } z > y. \end{cases}$$

Proof. The proof is similar to the one for Lemma B.1. It can be verified that

$$\det \begin{bmatrix} A_0^- \\ B_1^- e^{M_-} \end{bmatrix} = \begin{vmatrix} 1 & 0 \\ i\lambda_- e^{-i\lambda_-} & e^{-i\lambda_-} \end{vmatrix} = e^{-i\lambda_-} \neq 0,$$

So the Theorem A.1 implies that the problem (B.10)–(B.12) has a unique solution.

Let $\{A_-(y), r_-(y)\}$ and $\{B_-(y), s_-(y)\}$ be the integrated solutions of the problems (B.10), (B.11), and (B.10), (B.12), respectively. Taking

$$D_0^- = -i\lambda_-, \quad D_1^- = i\lambda_-,$$

we obtain from (A.7)–(A.10) that the integrated solutions satisfy

$$A'_- = A_- M_- - i\lambda_- A_-, \quad A_-(0) = A_0^-, \quad (\text{B.24})$$

$$r'_- = A_- \mathbf{f}_- - i\lambda_- r_-, \quad r_-(0) = u_-(0), \quad (\text{B.25})$$

and

$$B'_- = B_- M_- + i\lambda_- B_-, \quad B_-(y_-) = B_1^-, \quad (\text{B.26})$$

$$s'_- = B_- \mathbf{f}_- + i\lambda_- s_-, \quad s_-(y_-) = g_-. \quad (\text{B.27})$$

Upon solving the above initial value problem, we obtain the integrated solutions

$$A_- = [A_1^-, A_2^-] = \frac{1}{2i\lambda_-} [i\lambda_- (e^{-2i\lambda_- y} + 1), e^{-2i\lambda_- y} - 1], \quad (\text{B.28})$$

$$B_- = [B_1^-, B_2^-] = [i\lambda_-, 1], \quad (\text{B.29})$$

$$r_- = e^{-i\lambda_- y} u_-(0) + \int_0^y e^{-i\lambda_-(y-z)} A_2^-(z) f_-(z) dz, \quad (\text{B.30})$$

$$s_- = e^{-i\lambda_-(y-y)} g_- - \int_y^{y^-} e^{-i\lambda_+(z-y)} f_-(z) dz. \quad (\text{B.31})$$

An application of Gram's rule yields

$$u_- = \frac{r_- B_2^- - s_- A_2^-}{A_1^- B_2^- - B_1^- A_2^-}. \quad (\text{B.32})$$

A simple calculation yields

$$A_1^- B_2^- - B_1^- A_2^- = 1.$$

Substituting (B.28)–(B.31) into (B.32), we deduce (B.23). \square

To completely determine the solutions $u_+(y)$ and $u_-(y)$, it is required to compute $u_+(0)$ and $u_-(0)$, which can be obtained by using the jump conditions (B.5) and (B.6). Simple calculations yields

$$\begin{aligned} \partial_y K_1^+(0) &= -e^{i\lambda_+ y_+}, & \partial_y K_2^+(0, z) &= -e^{i\lambda_+ z}, \\ \partial_y K_1^-(0) &= e^{-i\lambda_- y_-}, & \partial_y K_2^-(0, z) &= -e^{-i\lambda_- z}, \end{aligned}$$

which gives

$$\begin{aligned} \partial_y u_+(0) &= i\lambda_+ u_+(0) + e^{i\lambda_+ y_+} g_+ - \int_0^{y_+} e^{i\lambda_+ z} f_+(z) dz, \\ \partial_y u_-(0) &= -i\lambda_- u_-(0) + e^{-i\lambda_- y_-} g_- + \int_{y_-}^0 e^{-i\lambda_- z} f_-(z) dz. \end{aligned}$$

It follows from the jump conditions (B.5) and (B.6) we obtain

$$u_-(0) = \frac{-i}{\lambda_+ + \lambda_-} \times \left[h_2 - i\lambda_+ h_1 + e^{-i\lambda_- y_-} g_- - e^{i\lambda_+ y_+} g_+ + \int_0^{y_+} e^{i\lambda_+ z} f_+(z) dz + \int_{y_-}^0 e^{-i\lambda_- z} f_-(z) dz \right] \quad (\text{B.33})$$

and

$$u_+(0) = u_-(0) + h_1. \quad (\text{B.34})$$

Theorem B.1. *Given $f_- \in L^1(y_-, 0)$, $f_+ \in L^1(0, y_+)$, and $g_{\pm} \in \mathbb{R}$. The transmission problem (B.1)–(B.6) has a unique solution explicitly expressed by (B.13) and (B.23) with $u_{\pm}(0)$ given by (B.33)–(B.34).*
