All sets and maps are definable in a polynomially bounded o-minimal structure over $\mathbb{R}$ with the field of exponents $\mathbb{F}$, e.g., semialgebraic or subanalytic with $\mathbb{F}=\mathbb{Q}$.

A set $X \subset \mathbb{R}^{n}$ inherits from $\mathbb{R}^{n}$ two metrics: the outer metric $\operatorname{dist}(x, y)=|y-x|$ and the inner metric $\operatorname{idist}(x, y)=$ length of the shortest path in $X$ connecting $x$ and $y$.
$X$ is normally embedded if these two metrics on $X$ are equivalent.

A surface germ is a closed two-dimensional germ $X$ at the origin.

Germs $X$ and $Y$ are outer (inner) Lipschitz equivalent if there is an outer (inner) bi-Lipschitz homeomorphism $X \rightarrow Y$.

For $\beta \in \mathbb{F}, \beta \geq 1$, the standard $\beta$-Hölder triangle is the set $\bar{T}_{\beta}=\left\{(x, y) \in \mathbb{R}^{2} \mid x \geq 0,0 \leq y \leq x^{\beta}\right\}$.

The standard $\beta$-horn is $C_{\beta}=\left\{(x, y, z) \in \mathbb{R}^{3} \mid z \geq 0, x^{2}+y^{2}=z^{2 \beta}\right\}$.

A $\beta$-Hölder triangle is a germ inner Lipschitz equivalent to $T_{\beta}$.
A $\beta$-horn is a germ inner Lipschitz equivalent to $C_{\beta}$.

Inner Lipschitz classification of surface germs: Birbrair 99.
Canonical decomposition of a surface germ $X$ into $\beta_{i}$-Hölder triangles with singular boundary arcs and $\beta_{j}$-horns.
Complete invariant of the inner Lipschitz equivalence class of $X$.

Finiteness theorems: Mostowski 85, Parusinski 94, Valette 05. Any definable family has finitely many outer Lipschitz equivalence classes.

Our goal: Outer Lipschitz classification of surface germs.
Decomposition of $X$ into normally embedded Hölder triangles, with some additional data, unique up to outer Lipschitz equivalence. Complete invariant of the outer Lipschitz equivalence class of $X$.

An arc $\gamma$ in $X$ is a germ of a map $\gamma:[0, \epsilon) \rightarrow X$ such that $|\gamma(t)|=t$.

The Valette link $V(X)$ is the space of all arcs in $X$.

Tangency order $\operatorname{tor} d\left(\gamma, \gamma^{\prime}\right) \in \mathbb{F} \cup\{\infty\}$ of $\gamma$ and $\gamma^{\prime}$ is the exponent $\kappa$ in $\left|\gamma-\gamma^{\prime}\right|=c t^{\kappa}+$ (higher terms), $c \neq 0$.

An arc is Lipschitz non-singular if it is an interior arc of a normally embedded Hölder triangle $T \subset X$. There are finitely many Lipschitz singular arcs in $V(X)$.

A Lipschitz singular arc may contain Lipschitz regular points of $X$.

A Hölder triangle is non-singular if all its interior arcs are Lipschitz non-singular.

A zone is a set $Z \subset V(X)$ such that for any arcs $\gamma \neq \gamma^{\prime}$ in $Z$ there is a non-singular Hölder triangle $T$ bounded by $\gamma$ and $\gamma^{\prime}$ such that $V(T) \subset Z$.

The order $\operatorname{ord}(Z)$ of a zone $Z$ is the infimum of tangency orders of arcs in $Z$. A singular zone $Z=\{\gamma\}$ has order $\infty$.

A zone $Z$ is closed if there are arcs $\gamma$ and $\gamma^{\prime}$ in $Z$ such that $\operatorname{tord}\left(\gamma, \gamma^{\prime}\right)=\operatorname{ord}(Z)$, otherwise $Z$ is open.

An arc $\gamma$ in a $\beta$-Hölder triangle $T=T\left(\gamma_{1}, \gamma_{2}\right)$, bounded by the arcs $\gamma_{1}$ and $\gamma_{2}$, is generic if $\operatorname{tord}\left(\gamma, \gamma_{1}\right)=\operatorname{tord}\left(\gamma, \gamma_{2}\right)=\beta$.

A zone $Z$ is perfect if, for any $\gamma \neq \gamma^{\prime}$ in $Z$, there is a Hölder triangle $T$ such that $V(T) \subset Z$ and both $\gamma$ and $\gamma^{\prime}$ are generic arcs of $T$.

Special case: pizza. Let $X$ be the union of a $\beta$-Hölder triangle $T$ in the $x y$-plane and a graph $z=f(x, y)$ of a Lipschitz function $f$ defined on $T$, such that $f(0,0)=0$.

The order of $f$ on $\gamma \subset T$ is $\operatorname{ord} d_{\gamma}=\operatorname{tord}\left(\gamma, \gamma^{\prime}\right)$ where $\gamma^{\prime}=(\gamma, f(\gamma))$. Let $Q(T) \subset \mathbb{F} \cup\{\infty\}$ be the set of $q=\operatorname{ord}_{\gamma} f$ for all $\gamma \subset T$.
The set $Q(T)$ is a closed interval in $\mathbb{F} \cup\{\infty\}$.
$T$ is elementary if $Z_{q}=\left\{\gamma \subset T, \operatorname{ord}_{\gamma} f=q\right\}$ is a zone for any $q \in Q(T)$. The width function on $Q(T)$ is defined as $\mu(q)=\operatorname{ord}\left(Z_{q}\right)$.
$T$ is a pizza slice if either $Q(T)$ is a single point, or $\mu(q)=a q+b$ is affine, where $a \neq 0$.

The boundary arc $\tilde{\gamma}$ of $T$ where $\mu$ is maximal is its supporting arc.

A pizza on $T$ associated with $f$ is a decomposition of $T$ into Hölder triangles $T_{j}$, each of them a pizza slice, with several toppings:

- exponent $\beta_{j}$ of $T_{j}$,
- closed interval $Q_{j}=Q\left(T_{j}\right)$ in $\mathbb{F} \cup\{\infty\}$,
- affine width function $\mu_{j}(q)$ on $Q_{j}$,
- supporting arc $\tilde{\gamma}_{j}$ of $T_{j}$ (when $Q_{j}$ is not a point),
- sign $s_{j}$ of $f$ on $T_{j}$ (not needed if $f$ is non-negative).

A pizza is minimal if the union of any two adjacent pizza slices is not a pizza slice.

Theorem (Birbrair et al. 17). The minimal pizza exists and is unique, up to bi-Lipschitz equivalence, for the Lipschitz contact equivalence class of $f$.

For a non-negative Lipschitz function $f$ on $T$, Lipschitz contact equivalence class of $f$ is the same as outer Lipschitz equivalence class of the union $X$ of $T$ and the graph of $f$.

All toppings of a minimal pizza are canonical, while the pizza slices $T_{j}$ are not. However, boundary arcs of Hölder triangles $T_{j}$ can be placed in canonical perfect zones $Z_{i} \subset V(T)$. Here is the plan:

1. Identify a canonical finite family of perfect boundary zones $Z_{i} \subset V(T)$ where boundary arcs of $T_{j}$ can be placed.
2. Choose arbitrary boundary arcs of Hölder triangles $T_{j}$ inside the zones $Z_{i}$. All choices define minimal pizzas for $f$, resulting in outer Lipschitz equivalent decompositions of $X$.
3. Replace this geometric construction with a canonical abstract combinatorial object to get outer Lipschitz invariant of $X$.

Example: $f(x, y)=y^{2}-x^{3}$. We have $\left.f\right|_{\gamma_{ \pm}} \equiv 0$, where $\gamma_{ \pm}=\left\{x \geq 0, y= \pm x^{3 / 2}\right\}$ are singular boundary zones. There are six boundary zones of finite order $\mu$ :

The set of arcs $\gamma$ such that $q=\operatorname{ord}_{\gamma} f=3$ consists of four zones: $Z_{+}, Z_{-}, Z_{0}, Z_{0}^{\prime}$. Each of them is perfect of order $\mu=3 / 2$. The set of arcs $\gamma$ such that $q=\operatorname{ord}_{\gamma} f=2$ consists of two zones: $Z_{+}^{\prime}$ and $Z_{-}^{\prime}$. Each of them is perfect of order $\mu=1$.

$$
\begin{aligned}
& \mathrm{q}=2, \mu=1 \quad Z_{+}^{\prime} \\
& \mathrm{q}=3, \mu=3 / 2 \quad Z_{0}^{\prime} \\
& Z_{+} \quad \mathrm{q}=3, \mu=3 / 2 \\
& \gamma_{+} \quad \mathrm{q}=\infty, \mu=\infty \\
& Z_{0} \quad \mathrm{q}=3, \mu=3 / 2 \\
& Z_{-} \quad \mathrm{q}=3, \mu=3 / 2
\end{aligned}
$$

A minimal pizza for $f$ consists of eight slices $T_{j}$ with the boundary arcs $\gamma_{+}, \gamma_{-}$and an arbitrary arc selected in each of the six other boundary zones.

$$
\begin{aligned}
& \beta_{3}=1 \\
& \beta_{4}=1 \quad Q_{3}=[2,3] \\
& \beta_{2}=3 / 2, Q_{2}=[3, \infty], \mu_{2}=q-3 / 2 \\
& Q_{4}=[2,3] \\
& \mu_{3}=q / 2 \\
& \beta_{1}=3 / 2, Q_{1}=[3, \infty], \mu_{1}=q-3 / 2 \\
& \beta_{5}=1 \\
& \beta_{8}=3 / 2, Q_{8}=[3, \infty], \mu_{8}=q-3 / 2 \\
& Q_{5}=[2,3] \\
& \begin{array}{l}
\beta_{6}=1 \\
Q_{6}=[2,3]
\end{array} \\
& \mu_{6}=q / 2
\end{aligned}
$$

General surface germ $X$ : normal and abnormal zones.
A Lipschitz non-singular arc $\gamma \subset X$ is abnormal if there are normally embedded Hölder triangles $T$ and $T^{\prime}$ in $X$ such that $\gamma=T \cap T^{\prime}$ and $T \cup T^{\prime}$ is not normally embedded. Otherwise, $\gamma$ is normal.

A zone $Z \subset V(X)$ is abnormal (resp., normal) if all arcs in $Z$ are abnormal (resp., normal).

An abnormal (resp., normal) zone is maximal if it is not contained in a larger abnormal (resp., normal) zone.

Theorem (AG, Souza 21) For any surface germ $X$, there is a canonical partition of $V(X)$ into finitely many maximal abnormal and maximal normal zones. All normal zones are normally embedded. All maximal abnormal zones are closed perfect and weakly normally embedded.

Snakes, circular snakes, bubble snakes and non-snake bubbles.
A $\beta$-snake is a non-singular $\beta$-Hölder triangle $T$ such that each arc in $V(T)$ is abnormal iff it is generic. A maximal abnormal $\beta$-zone $Z \subset V(X)$ is a snake zone if there is a $\beta$-Hölder triangle $T \subset X$ such that $Z \subset V(T)$.

A circular $\beta$-snake is a $\beta$-horn $C$ such that all arcs in the circular $\beta$-snake zone $V(C)$ are abnormal.

A bubble is a Hölder triangle $T$ bounded by $\gamma_{1}$ and $\gamma_{2}$, such that $\operatorname{tord}\left(\gamma_{1}, \gamma_{2}\right)>\operatorname{itord}\left(\gamma_{1}, \gamma_{2}\right)$, partitioned into normally embedded triangles by an arc $\gamma$. A bubble snake is a bubble that is a snake.
A non-snake bubble is a bubble that does not contain a snake.
A non-snake abnormal zone is a maximal abnormal zone $Z \subset V(T)$ where $T$ is a non-snake bubble.

bubble snake

non-snake bubbles with $\eta<\beta$

Theorem (AG, Souza 21) Each maximal abnormal $\beta$-zone in $V(X)$ is either a $\beta$-snake zone, or $V(C)$ where $C$ is a circular $\beta$-snake, or a non-snake abnormal $\beta$-zone $Z \subset V(T)$ where $T$ is a non-snake $\eta$-bubble for some $\eta<\beta$.
Each non-snake abnormal $\beta$-zone is closed perfect and normally embedded.

Each maximal $\beta$-snake zone, and each circular $\beta$-snake zone, has a canonical partition into finitely many normally embedded $\beta$-zones: closed perfect segments and open perfect nodal zones.
A boundary nodal zone of a $\beta$-snake zone $Z$ is a normal zone where a boundary arc of a $\beta$-snake $T$ may be placed, so that $Z$ is the set of generic arcs of $T$.
Each boundary nodal zone is an open, normally embedded $\beta$-zone. If it is not perfect, then it contains either a Lipschitz singular arc or a perfect boundary nodal zone of an $\alpha$-snake, for some $\alpha>\beta$, or it is adjacent to a non-snake abnormal $\alpha$-zone, for some $\alpha>\beta$.

Segments, nodal zones (red) and boundary nodal zones (green).

Outer Lipschitz invariant decomposition of a surface germ $X$.
A pair ( $T, T^{\prime}$ ) of normally embedded Hölder triangles is transversal if $T \cup T^{\prime}$ is a subset of a normally embedded triangle.

A non-transversal pair ( $T, T^{\prime}$ ) is coherent if it is outer Lipschitz equivalent to the union of a pizza slice $T$ for a Lipschitz function $f$ and the graph $T^{\prime}$ of $f$ over $T$.

Step 1. Define canonical primary zones in $V(X)$ as

- Lipschitz singular arcs,
- Maximal normal zones,
- Segments and nodal zones of snake zones and circular snakes,
- Boundary nodal zones of snakes,
- Non-snake abnormal zones.

Step 2. Using pizza decomposition for the "distance functions" between primary zones, define secondary zones in $V(X)$ so that minimal (by inclusion) secondary zones are perfect.

Step 3. Placing boundary arcs in minimal secondary zones, decompose $X$ into finitely many isolated arcs and normally embedded Hölder triangles, so that any two triangles are either coherent or transversal, and all choices of arcs result in outer Lipschitz equivalent decompositions.

This step involves proper order in which the boundary arcs are placed, starting with isolated arcs and Lipschitz singular arcs.

Extra tertiary zones are associated with some boundary arcs, where more boundary arcs should be placed.

Example: Secondary zones in Step 2

Example: Tertiary zones in Step 3

## Main Theorem.

There is a unique up to outer Lipschitz equivalence decomposition of a surface germ $X$ into isolated arcs and normally embedded Hölder triangles, such that any two triangles are either coherent or transversal.

Two such decompositions are combinatorially equivalent if there is one-to-one correspondence between their arcs and triangles, preserving adjacency relations, tangency exponents between any two isolated arcs and/or boundary arcs of triangles, and pizza toppings for the distance between any two coherent triangles: interval $Q \subset \mathbb{F} \cup\{\infty\}$, width function $\mu(q)=$ $a q+b$ on $Q$, supporting arc $\tilde{\gamma}$.

Two surface germs are outer Lipschitz equivalent if and only if their canonical decompositions are combinatorially equivalent.
