## SOLUTIONS TO HOMEWORK 12

1. (a) Since the equation $x^{2}-5 y^{2}=1$ has the solution $(x, y)=(9,4)$, we know that $(x, y)=\left(9^{2}+5 \cdot 4^{2}, 2 \cdot 9 \cdot 4\right)=(161,72)$ also solves this equation.
(b) Suppose that $x^{2}-5 y^{2}=1$ has just finitely many solutions, and let $(x, y)$ be the solution with $x$ largest. Then $\left(x^{2}+5 y^{2}, 2 x y\right)$ is a solution with $x^{2}+5 y^{2}>x$, giving a contradiction. So the equation has infinitely many integral solutions. (c) One can check that $5^{2}-5 \cdot 2^{2}=25-20=5$, and so $(u, v)=(5,2)$ solves $u^{2}-5 v^{2}=5$. Suppose that $(x, y)$ is a solution of $x^{2}-5 y^{2}=1$. Consider the real number $(5+2 \sqrt{5})(x+y \sqrt{5})=(5 x+10 y)+(2 x+5 y) \sqrt{5}$. Motivated by multiplication by the conjugate, one finds that

$$
(5 x+10 y)^{2}-5(2 x+5 y)^{2}=5\left(x^{2}-5 y^{2}\right)=5 .
$$

Since from part (b) there are infinitely many solutions $(x, y)$ of $x^{2}-5 y^{2}=1$, then there are infinitely many solutions $(u, v)=(5 x+10 y, 2 x+5 y)$ of the equation $u^{2}-5 v^{2}=5$.
2. (a) Recall that $\sqrt{6}=[2 ; \overline{2,4}]$. We compute the convergents $p_{n} / q_{n}$ to the continued fraction expansion of $\sqrt{6}$, using the recurrence relations from class:

$$
\begin{aligned}
& \frac{p_{0}}{q_{0}}=\frac{2}{1} \quad \text { and } \quad p_{0}^{2}-6 q_{0}^{2}=2^{2}-6 \cdot 1^{2}=-2, \\
& \frac{p_{1}}{q_{1}}=\frac{2 \cdot 2+1}{2} \quad \text { and } \quad p_{1}^{2}-6 q_{1}^{2}=5^{2}-6 \cdot 2^{2}=1,
\end{aligned}
$$

so the fundamental solution of $x^{2}-6 y^{2}=1$ is $(x, y)=(5,2)$. Thus, every solution $(x, y)$ of $x^{2}-6 y^{2}=1$ is given by $x+y \sqrt{6}= \pm(5+2 \sqrt{6})^{n}(n \in \mathbb{Z})$.
(b) We have $\sqrt{54}=[7 ; \overline{2,1,6,1,2,14}]$. We compute the convergents $p_{n} / q_{n}$ to the continued fraction expansion of $\sqrt{54}$, using recurrence relations from class:

$$
\begin{aligned}
& \frac{p_{0}}{q_{0}}=\frac{7}{1} \quad \text { and } \quad p_{0}^{2}-54 q_{0}^{2}=7^{2}-54 \cdot 1^{2}=-5 \\
& \frac{p_{1}}{q_{1}}=\frac{2 \cdot 7+1}{2} \quad \text { and } \quad p_{1}^{2}-54 q_{1}^{2}=15^{2}-54 \cdot 2^{2}=9 \\
& \frac{p_{2}}{q_{2}}=\frac{1 \cdot 15+7}{1 \cdot 2+1} \quad \text { and } \quad p_{2}^{2}-54 q_{2}^{2}=22^{2}-54 \cdot 3^{2}=-2, \\
& \frac{p_{3}}{q_{3}}=\frac{6 \cdot 22+15}{6 \cdot 3+2} \quad \text { and } \quad p_{3}^{2}-54 q_{3}^{2}=147^{2}-54 \cdot 20^{2}=9, \\
& \frac{p_{4}}{q_{4}}=\frac{1 \cdot 147+22}{1 \cdot 20+3} \quad \text { and } \quad p_{4}^{2}-54 q_{4}^{2}=169^{2}-54 \cdot 23^{2}=-5, \\
& \frac{p_{5}}{q_{5}}=\frac{2 \cdot 169+147}{2 \cdot 23+20} \quad \text { and } \quad p_{5}^{2}-54 q_{5}^{2}=485^{2}-54 \cdot 66^{2}=1,
\end{aligned}
$$

so the fundamental solution of $x^{2}-54 y^{2}=1$ is $(x, y)=(485,66)$. Thus, the solutions $(x, y)$ of $x^{2}-54 y^{2}=1$ are given by $x+y \sqrt{54}= \pm(485+66 \sqrt{54})^{n}$ $(n \in \mathbb{Z})$.
3. We know that there are infinitely many integral solutions $(x, y)$ to the Pell equation $x^{2}-d y^{2}=1$ with $x>1$ and $y>1$. In particular, we have $(x, y)=1$ and $x=\sqrt{d y^{2}+1}>y \sqrt{d}$. Thus, since $(y \sqrt{d}-x)(y \sqrt{d}+x)=-1$, we see that

$$
|y \sqrt{d}-x|=\frac{1}{|y \sqrt{d}+x|}<\frac{1}{2 y \sqrt{d}},
$$

whence $|\sqrt{d}-x / y|<1 /\left(2 \sqrt{d} y^{2}\right)$. Since there are infinitely many such pairs $(x, y)$, the desired conclusion follows.
4. Let $(p, q)$ denote the solution of $x^{2}-d y^{2}=1$ with $p, q \in \mathbb{N}$ and with $p, q$ smallest. Then the set of all solutions of $x^{2}-d y^{2}=1$ is given by $\pm\left(A_{m}, B_{m}\right)$ with $m \in \mathbb{Z}$, where $A_{m}, B_{m}$ are the integers determined from the relation $A_{m}+B_{m} \sqrt{d}=(p+q \sqrt{d})^{m}$. In particular, these solutions satisfy $A_{m+1}>A_{m}$ for $m \in \mathbb{N}$, and similarly $B_{m+1}>B_{m}$. Also, one has
$A_{m+1}+B_{m+1} \sqrt{d}=(p+q \sqrt{d})\left(A_{m}+B_{m} \sqrt{d}\right)=\left(p A_{m}+d q B_{m}\right)+\sqrt{d}\left(q A_{m}+p B_{m}\right)$, and

$$
\begin{aligned}
A_{m+2}+B_{m+2} \sqrt{d} & =(p+q \sqrt{d})^{2}\left(A_{m}+B_{m} \sqrt{d}\right) \\
& =\left(\left(p^{2}+q^{2} d\right) A_{m}+2 d p q B_{m}\right)+\sqrt{d}\left(2 p q A_{m}+\left(p^{2}+d q^{2}\right) B_{m}\right)
\end{aligned}
$$

Consequently,

$$
\begin{aligned}
A_{m+2}-2 p A_{m+1} & =\left(\left(p^{2}+d q^{2}\right) A_{m}+2 p q d B_{m}\right)-2 p\left(p A_{m}+d q B_{m}\right) \\
& =\left(d q^{2}-p^{2}\right) A_{m}=-A_{m},
\end{aligned}
$$

and

$$
\begin{aligned}
B_{m+2}-2 p B_{m+1} & =\left(\left(p^{2}+d q^{2}\right) B_{m}+2 p q A_{m}\right)-2 p\left(q A_{m}+p B_{m}\right) \\
& =\left(d q^{2}-p^{2}\right) B_{m}=-B_{m} .
\end{aligned}
$$

So the sequence of positive solutions $\left(x_{n}, y_{n}\right)$ of $x^{2}-d y^{2}=1$, written according to increasing values of $x$ or $y$, satisfies $u_{n+2}-2 p u_{n+1}+u_{n}=0(u=x$ or $y)$, where $p$ is the smallest positive integer such that $p^{2}-d q^{2}=1$ is soluble with $q \in \mathbb{N}$.
