- Correcting the logarithm of the sketch

3 Numerical results

3 > 4 3

Motivation

• Paradigm: We consider the elliptic boundary value problem

$$\nabla \cdot p \nabla u = f \quad \text{in } \Omega,$$

$$\alpha u + \beta p \nabla u \cdot \hat{n} = g \quad \text{on } \partial \Omega,$$

on a simply connected domain $\Omega \subset \mathbb{R}^d$, $d = \{2, 3\}$ with smooth boundary $\partial \Omega$ where the unit normal is \hat{n} and α , β , f and g are chosen such that u is unique.

- **Applications**: Engineering simulation, uncertainty propagation and statistical inverse problems.
- Focus: Computing a numerical approximation of u(p) for many parameter fields p (diagonal tensors).

・ロト ・ 同ト ・ ヨト ・ ヨト

An example in electrostatics: Neumann problem

Left: a discrete profile of p on a disk with 9k nodes and 28k elements. Right: a numerical solution u(p) with $f = \alpha = 0$, $\beta = 1$ and $\int_{\partial\Omega} g ds = 0$ conditions. 3D grids can have $> 10^6$ nodes.

Nick Polydorides (UoEdinburgh)

Galerkin finite elements

In Galerkin FEM with linear basis the BVP yields a linear system

$$Au = b$$
,

with

$$A := (P^{\frac{1}{2}}D)^{T}(P^{\frac{1}{2}}D)$$

where $P \in \mathbb{R}^{N \times N}$ is a positive diagonal, and $D \in \mathbb{R}^{N \times n}$ a tall sparse matrix with *i*-th row $D_{(i)}$ and N > n.

- The elements of *P* are the discretised model parameters of the PDE.
- A is $n \times n$ real, sparse, symmetric, positive definite.
- We consider *n* to be very large.

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

Projected (again) FEM equations: POD

• Given P we seek to approximate the high-dimensional solution u_{opt} of

Au = b,

with $u_{reg} \in \mathbb{S}$ that solves the projected equation

 $\Pi A u = \Pi b$

where $\Pi : \mathbb{R}^n \to \mathbb{S}$ is the projection onto

 $\mathbb{S} := \{\Psi r \mid r \in \mathbb{R}^s\}$

and $\Psi^T \Psi = I$ and $s \ll n$.

Assumptions:

• Choice of basis: $u_{opt} \approx \Pi u_{opt} = \Psi \Psi^T u_{opt}$,

• Existence of u_{reg} : $I - \Pi(I - A)$ is invertible $\iff A$ is invertible for Ψ ON.

Projection

Projected FEM equations

• Substituting $u_{\rm reg} = \Psi r_{\rm reg}$ into the projected equation yields an $s \times s$ system

$$\mathbf{G} \mathbf{r} = \mathbf{\Psi}^{\mathsf{T}} \mathbf{b},$$

where

$$G := \Psi^{\mathsf{T}} A \Psi = \Psi^{\mathsf{T}} (P^{\frac{1}{2}} D)^{\mathsf{T}} (P^{\frac{1}{2}} D) \Psi = (P^{\frac{1}{2}} X)^{\mathsf{T}} (P^{\frac{1}{2}} X)$$

and $X \in \mathbb{R}^{N \times s}$ tall having *i*-th row $X_{(i)} := D_{(i)} \Psi$ and rank $(X) = s$.

 The special case P = I corresponds to the homogeneous PDE and a projected system

$$Q r = \Psi^T b_s$$

and note that G and Q are similar

$$G = \sum_{i=1}^{N} p_i Q_i$$
, while $Q := \sum_{i=1}^{N} Q_i$, with $Q_i := X_{(i)}^T X_{(i)}$.

Nick Polydorides (UoEdinburgh)

Sketching the projected equations

• The plan is to estimate $\hat{G} = (SP^{\frac{1}{2}}X)^T (SP^{\frac{1}{2}}X)$ from $c \ll N$ iid samples $\{i_1, \ldots, i_c\} \in \{1, \ldots, N\}$ using a suitable sketching matrix S, then

$$\hat{G}\hat{r} = \Psi^{T}b \quad \longrightarrow \quad \hat{u}_{\mathsf{reg}} = \Psi\hat{G}^{-1}\Psi^{T}b$$

• The sketch \hat{G} must be invertible with very high probability:

$$\|\hat{G}^{-1}G - I\| \to \min$$

- The sketch \hat{G} should have low-variance, better than MC.
- Sketching linear equations involving the Laplacian matrix of a graph. (Drineas & Mahoney, 2010)

Sketching invertible matrices

• Consider first $Q = X^T X$ with $u_{reg} = \Psi Q^{-1} \Psi^T b$, $\hat{u}_{reg} = \Psi \hat{Q}^{-1} \Psi^T b$ and $X = U_X \Sigma_X V_X^T$. The sketching error is bounded by

$$\|u_{\mathsf{reg}} - \hat{u}_{\mathsf{reg}}\| \le \|\hat{Q}^{-1}Q - I\| = \|\Sigma_X^{-1}(U_X^T S^T S U_X)^{-1} \Sigma_X - I\|,$$

conditioned on $\hat{Q} = (SX)^T SX$ being invertible.

- How do we choose *S* ?
- We argue S must be such that $U_X^T S^T S U_X \approx I$ in spectral norm, which for $||U_X^T S^T S U_X I|| < \epsilon < 1$ guarantees

$$1-\epsilon \leq \frac{\|U_X^T S^T S U_X - I\|}{\|(U_X^T S^T S U_X)^{-1} - I\|} \leq 1+\epsilon.$$

< 口 > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

Leverage score sampling without replacement

- $\hat{Q}^{-1} \rightarrow \|\hat{u}_{reg} u_{reg}\|$ bounded $\rightarrow U_X^T S^T S U_X \approx I$ in spectral norm \rightarrow design sketch S.
- Let $\ell_i(X) = ||U_{X(i)}||^2$ be the leverage score of $X_{(i)}$ and ξ a distribution with element

$$\xi_i = \ell_i(X)/s > 0, \quad i = 1, \dots, N,$$

then sampling each row of X independently with probability

$$\eta_i = \min\{1, c'\xi_i\}$$

where c' is an upper bound on the sample size, then by (Tropp, 2015)

$$\mathbb{P}(\|U_X^{\mathsf{T}}S^{\mathsf{T}}SU_X - I\| \ge \epsilon) \le 2s \exp\left(-\frac{3c'\epsilon^2}{6s + 2s\epsilon}\right), \quad \forall \epsilon > 0.$$

10/27

Approximate leverage scores

- Sampling based on $\ell(X)$ yields virtually always an invertible \hat{Q} . We are however interested in $\hat{G} = (SP^{\frac{1}{2}}X)^T (SP^{\frac{1}{2}}X)$ not $\hat{Q} = (SX)^T SX$.
- The desirable invertibility is preserved even when the rows of X are re-weighted by positive scalars through P^{1/2}.
- Proposition: Let S be a sketching sparse diagonal matrix with rows

$$S_{(i)} = rac{\gamma_i}{\sqrt{\eta_i}} e_i^T, \quad i = 1, \dots, N,$$

where e_i the *i*-th column of *I*, and γ_i is a Bernoulli variable with $\mathbb{P}(\gamma_i = 1) = \eta_i$ then

$$\mathbb{P}(\hat{G}^{-1} \text{ exists}) = \mathbb{P}(\hat{Q}^{-1} \text{ exists}) \ge 1 - 2s \exp\left(-\frac{3c}{8s}\right).$$

Nick Polydorides (UoEdinburgh)

Approximate leverage scores - invertibility guarantees

- Key idea: To sketch G based on the leverage scores of X which can be pre-computed offline.
- We can show that $\hat{G} \succ 0$ when $\hat{Q} \succ 0$ by exploiting the commutative property of diagonal matrices

$$\hat{Q} \succ 0 \Longleftrightarrow U_X^T S^T S U_X \succ 0$$

• With $P \succ 0$ and rank $(X) = s \implies U_X^T S^T PSU_X \succ 0$ since

 $\hat{G} = X^T P^{\frac{1}{2}} S^T S P^{\frac{1}{2}} X = X^T S^T P S X = V_X \Sigma_X (U_X^T S^T P S U_X) \Sigma_X V_X^T$

• Rescaling the rows of X by some positive values $P^{\frac{1}{2}}$ preserves the invertibility iff $U_X^T S^T S U_X \succ 0$.

Nick Polydorides (UoEdinburgh)

12/27

Controlling complexity

- To get $c \approx s \log s + m$ samples we sample without replacement using $\eta_i = \min\{1, c'\xi_i\}$ where c' is an upper bound on samples.
- For a given c' the invertibility probability bound depends on the ratio c/s, where c is the actual number of samples.
- For a target error ϵ in $\mathbb{P}(||U_X^T S^T S U_X I|| \ge \epsilon)$ the choice of c' should be made independently of the high dimension N and around $\mathcal{O}(\epsilon^{-2} s \log s)$.
- Alternatively we may fix the expected number of sample $c_e = \sum_{i=1}^{N} \eta_i$ and compute the corresponding c' by finding the root of the monotonic

$$c' = \arg\left\{c_e - \sum_{j=1}^{N} \min\left\{1, c'\xi_j\right\}\right\} = 0.$$

Remarks on leverages

- Sampling O(s log s) ≪ N rows of (P^{1/2}X) the probability of invertibility failure is infinitesimally small.
- These remarks are consistent to the results in (Cohen et al., 2015) describing the change in leverage scores & matrix coherence after re-weighting a single row.
- Invertibility breaks down if the elements of $P^{\frac{1}{2}}$ vary wildly. This causes $A = (P^{\frac{1}{2}}D)^T (P^{\frac{1}{2}}D)$ to be ill-conditioned, u_{opt} unstable.
- Using the leverage scores suited for Q to sketch G, invertibility is preserved at the cost of higher variance.
- Estimating the leverage scores on-the-fly when solving over-determined LS problems, e.g. (Drineas et al., 2012).

Numerical results

(B)

Sketching G with control variate Q

- The elements of $\hat{G} = (SP^{\frac{1}{2}}X)^T (SP^{\frac{1}{2}}X)$ and $\hat{Q} = (SX)^T (SX)$ are positively correlated.
- Variance is similarly distributed between \hat{G}_{ij} and \hat{Q}_{ij} .
- Since Q does not depend on P we can compute it a priori, and subsequently sketch it along with G.
- Compute a new estimator with lower variance after applying an element-wise correction to the sketched \hat{G} as

$$\tilde{G} = \hat{G} - W \circ (Q - \hat{Q}),$$

where \circ denotes Shur product, and W is $s \times s$ symmetric

$$W_{ij} := rg \min {\sf Var}(ilde{G}_{ij}) = rac{{\sf Cov}(\hat{G}_{ij},\hat{Q}_{ij})}{{\sf Var}(\hat{Q}_{ij})}.$$

Control variates

Considering the control variates estimator

$$ilde{G} = \hat{G} - W \circ (Q - \hat{Q}),$$

notice that although $\hat{G} \succ 0$ with very high-probability, \tilde{G} is indefinite and thus \tilde{G}^{-1} may not exist.

• To preserve invertibility and reduce variance we may correct the matrix logarithm of \hat{G} instead

$$\widetilde{\log G} = \log \hat{G} - W \circ (\log Q - \log \hat{Q}).$$

• Rational: Compute an estimator whose expectation is log G and then take its matrix exponential to get a positive definite estimator of G.

Logarithmic control variates

• The log control variates estimator

$$\widetilde{\log G} = \log \hat{G} - W \circ (\log Q - \log \hat{Q}).$$

has two important shortcomings:

- Bias($\log G$) \neq 0, and it is not computationally tractable.
- The variances and covariances needed for W_{ij} are only available for sample batches, i.e. log Q_i = log(X^T_(i)X_(i)) is not well defined.
- To rectify this we propose to work with a finite expansion of the Neumann series for the matrix log,

$$\log(M) = \sum_{k=1}^{\infty} \frac{(-1)^{k+1}}{k} (M-I)^k \approx (M-I) - \frac{1}{2} (M-I)^2 := \mathcal{F}(M)$$

Preconditioning

 \bullet To ensure that the transform ${\mathcal F}$ converges to the log fast we sketch instead

$$\mathcal{F}(C_0^T Q C_0)$$
, and $\mathcal{F}(C^T G C)$,

for some choices of invertible preconditioners $C_0, \ C \in \mathbb{R}^{s \times s}$ such that

$$C_0^T Q C_0 \approx I$$
 and $C^T G C \approx I$.

• This yields an estimator

$$\widetilde{\log(C^{T}GC)} = \left(\mathcal{F}(C^{T}\hat{G}C) - B_{1}\right) - W \circ \left(\mathcal{F}(C_{0}^{T}\hat{Q}C_{0}) - B_{2}\right)$$

for some bias correction matrices B_1 and B_2 and thus arriving at the sought

$$\widetilde{G}^{-1} = C \exp\left(\log(\widetilde{C^{T}GC})\right) C^{T}$$

Nick Polydorides (UoEdinburgh)

19/27

A two-sample estimator

- The optimal choice of preconditioners C₀ and C requires knowledge of Q and G.
- Q is known a priori but G is not as it depends on P.
- A way around this is to utilise two independent samples based on the same Bernoulli probabilities.
- Use the first sample to obtain a sketched approximation of G in order to get C and C₀ (involves one SVD of an s × s matrix).
- Use the second sample to estimate \$\mathcal{F}(C_0^T \hat{Q} C_0)\$, \$\mathcal{F}(C^T \hat{G} C)\$ and compute weights

$$W_{ij} = \frac{\operatorname{Cov}\left(\mathcal{F}(C^{T}\hat{G}C)_{ij}, \mathcal{F}(C_{0}^{T}\hat{Q}C_{0})_{ij}\right)}{\operatorname{Var}\left(\mathcal{F}(C_{0}^{T}\hat{Q}C_{0})_{ij}\right), \quad \text{for } i \in \mathbb{R}, \quad i \in \mathbb{R},$$

20 / 27

Further implementation details

- The choice of projection basis Ψ (in $X = D\Psi$) requires solving a large-scale eigenvalue problem off-line, or using a snapshots-derived ON basis.
- The low-dimensional bias correction matrices $B_1(\eta, X, P)$ and $B_2(\eta, X)$ are needed. B_2 can be computed off-line but B_1 must be approximated.
- Sketching $C_0 Q C_0$ and $C^T G C$ is equivalent to sampling the rows of two tall matrices with ON columns. This is not the case in sampling directly Q and G.

- Averages of 100 solves with same right hand side b. The 100 P profiles where sampled from a lognormal random field with a smooth Whittle-Matérn covariance function.
- Note the errors in the last two columns are inclusive of the subspace approximation error.

Nick Polydorides (UoEdinburgh)

Conclusions

- Our approach decouples invertibility and accuracy of the sketched projected matrix estimator.
- Empirical results show the CV estimator suppresses sketching error by an order of magnitude.
- Low variance pays off when the subspace approximation error is small.
- Is it more efficient than estimating quickly the leverage scores?
- Further accuracy improvements via few iterations of a 'smoother' Jacobi iterative method.
